Inflammation of the fallopian tubes and ovaries and the peritoneum which surrounds and is in relation with them, is very common, and the inflammation generally presents itself in attacks or recurrences. It is very rare that an inflamed tube is restored to perfect health, and an ovary once inflamed never escapes lasting injury. Inflammation of the tubes as a rule, is primarily of the mucous lining, extending outward from the uterus to the fimbriated extremity, thence to the contiguous peritoneum. The irritant that produces pelvic peritonitis almost always comes from without. The exciting cause almost without exception, is septic material introduced into the vagina and uterus.

The first effect of a septic material so carried up until it reaches the peritoneum,

* Read before the Mitchell District Medical Society at West Baden Springs, July 13, 1893.

is inflammation of that membrane. Rapidly it responds and its first effort is to throw out inflammatory lymph, by which process it first seals up the fimbriated extremity of the tube and thus prevents the exit of any more poisonous or irritating material. The lymph exudate does not stop here, but more is poured out as the inflammatory process goes on, until the tube is enclosed and walled off from the rest of the pelvic and abdominal cavity. While this has been going on the uterine end of the tube has also become occluded by the infiltration of the tissues until the fallopian tube is hermetrically sealed at both ends and lies enclosed in a protective capsule of natures aseptic lymph.

This is a hasty explanation of what takes place in the pelvis at the beginning of an attack of pelvic inflammation. Now what symptoms does it present, what are the signs by which we recognize that this process is taking place? Most frequent and constant of all symptoms is pain, and localized to the ovarian regions. Most of the patients will cover with the point of the finger the spot at which they first felt pain, and with great uniformity they place the finger over the site of the ovary. The pain is most acute, and in some cases amounts to an agony. I need not dwell upon this point, for every physician here knows how severe the pain of a peritonitis may become. Then tenderness and high temperature quickly supervene. Nature's battles between tissue destroying and tissue preserving elements is always attended with fire.

There is not infrequently a chill to denote that a battle is on, and rising temperature and pulse at once begin. So pain, fever, tenderness, swelling, tympanites rapid pulse, all are consequent upon this process. The tenderness over the abdomen is nothing to the tenderness of the tissues touched by the examinining finger about the uterus. Swelling of the uterus, lumps in either side and cul de sac, painful lumps, masses, loops of tube, misplaced inflamed ovary, all the organs on fire, this is what will be found in an early stage. Gradually however, under treatment these symptoms subside. The pain gets better, but the soreness persists for a longer time. It may be days or weeks before she can move without pain, and it may be that never again will she be free from that soreness and lameness and tenderness that results from this condition. The ovary and tube may be folded upon themselves, wrapped up in the broad ligament and enclosed. Menstruation occuring soon is liable to light it all up and set it all going over again. A function that once was easy and natural now becomes a torture. Instead of a few days it may last many. The engorgement of the parts at the monthly epochs only excite again the inflammation. Every day, nature makes more effort to protect its inflamed part, bands of adhesions fasten the uterus and drag it into unnatural positions. In short, the inflamed tube adheres to every thing it touches and these adhesions become in time so dense and hard that, as one of my friends has said, "this mass has grown fast to every thing but her soul."

In case the irritant that has set up this process contains pus producing microbes we will have a much more serious state of affairs confronting us. The pus may be in such small quantity that it may become encased as it were in a small portion of the tube and the surrounding tube thickened to an extreme degree, constituting the so-called parenchymatous salpingitis or pachy salpingitis. I have a specimen of this kind from a case of my own, from the cut surface of which pus could be squeezed. In such cases the adhesions are liable to be very abundant owing to the greater effort made to shut off the pus from the general peritoneal cavity. The hardness and density of the adhesions as well as the malposition of organs will depend of course on the degree of inflammation and the length of time it has gone on. In cases where pus forms in the tube the temperature is liable to be very erratic. It may be very high or on the other hand hardly above normal, but the persistence of the fever is what guides us to the presence of pus. These cases of pus in the tube also are the ones in which ugly perforation of the bowel may occur. The pus may burrow and abcesses point in the vagina or near the rectum, and sinuses are left which refuse to heal because a diseased sloughing tube remains as a nidus. These abcesses and sinuses are only natures poor efforts at laparotomy. The pus must get away. No longer is she able to wall it in, but she must evacuate it.

Given then a case of pelvic inflamma-

tion, what plans of treatment can we pursue to allay the inflammation and if possible to prevent formation of pus. As for the treatment of pus cases there is only one course to pursue and that is operation. As a rule, however, these are not cases of pus from the start, and it is to the cases of inflammation not purulent in character that our plans of treatment must be directed.

The first indication is to relieve pain and this can be done in most instances best by early adminstration of saline purgatives. Epsom salts in saturated solution is the quickest an most rational method of lessoning pain. It empties the bowels. It abstracts moistures from the tissues. It drains the engorged pelvic vessels and diminishes blood supply to the inflamed part by bleeding one vessel into another. Those of us who are still wedded to the opium treatment of peritonitis will smile with incredulity at the assertion that the pain can be relieved with salts, yet such is the fact and if you don't believe it, try it.

Glycerine into the rectum is another way to relieve the pain quickly, and it does so in the same manner by setting up an outward osmatic current and lessening the engorgement of the tissues. Another drug that is of splendid service is the salicylate of ammonia. Give it in 3 grain doses every two hours and it will lower the temperature, stimulate the heart and kidney, eliminate rapidly from the circulation waste material and is the most reliable intestinal antiseptic that we possess. It is at the same time a valuable antipyretic and possesses analgesic properties only a little inferior to acetanilid. I pass over many other drugs of whose action you know so well, and speak of the local treatment. In the first few days it will be almost impossible to use any treatment whatever locally. The pain and tenderness is so great that it cannot be tolerated, but after free purgation we can apply loose tampons of glycerine over the irregular masses that can be felt under the finger. The effect is sometimes very striking. The swelling is frequently rapidly reduced, but much depends on how the applications are made. No good can come of placing them against the cervix, they must be against the painful tube, slightly lifting it and supporting it, but never making hard pressure. After the tenderness has grown less and after a few days have elapsed, the negative pole of a galvanic battery may be applied. Once every 48 hours is enough and not over 20 milleamperes for not over ten minutes. The effect upon the pain from this application is not infrequently simply wonderful and certainly the swelling does diminish. I cannot be mistaken surely in the effect that I have seen produced, notwithstanding so much has been said by better men against it. Under its influence I have certainly seen lumps, masses, hard tender masses in the broad ligaments disappear, the uterus become movable and the hardness of the vaginal vault disappear. I certainly have seen the effect in some cases, and then again I have just as certainly seen all my best efforts fail and the only thing I could effect was amelioration.

The masses could be made to grow smaller and less tender but they would not go away. The temperature would not go so high but would persist. The uterus was more movable but still fixed and misplaced. The pain was not so great but it was still there. She could maybe straighten out her leg, but for the most part it felt easier to draw it up. The night sweats were troublesome, and although she could sleep some at night, she would have a tired, worn look in her face in the morning. One day better, the next worse. Pain, disappointment, feebleness, tenderness, suffering and chronic invalidism staring us in the face; in short my patient's life was endangered and her health ruined by a something in her pelvis. Many of you have seen cases that so went on, month after month, you were discharged and some one else tried and so on. Now what is the best thing to do with these cases that do not get well. They won't get well. Nature is powerless; art must aid. Abdominal section offers the most brilliant and successful page of modern medicine and surgery in the treatment of these very cases of chronic inflammation of the pelvic viscera. Open the abdomen and remove the source of the disease. Most of the cases will recover under treatment and rest and proper care, but some will find their only relief at the hand of the surgeon. We are able to-day to cure many an invalid that only a few years ago was resigned to opium and an early grave. Cases that only a few years ago would have come under that now rapidly diminishing list-incurable, can now be not only saved but cured, to stay cured and fill a useful place in society.

# THE TREATMENT OF CARBUNCLE BY CARBOLIC ACID INJECTIONS.

C. H. WILKINSON, M. D.,* Galveston, Texas.

On June 11th, 1893, I was called to attend Mrs. S., living some twenty-one miles in the country, for a carbuncle which had existed a week.

I found the lady in bed, with high fever, and apparently suffering severe pain from the effects of a carbuncle situated immediately under the right scapula, and which with its highly inflamed and sensitive areola was about the size of a large saucer. From long continued pain the patient's nervous system had become highly wrought up, and long fasting had reduced her strength to that of a child. Selecting four of the most conspicuous sinuses perforating the growth, I injected into each one of them a solution containing two minims of carbolic acid, throwing the remedy in each instance out towards the periphery of the tumor, and towards the most highly inflamed portions. Directing her to keep hot poultices applied to the diseased parts until all suppuration had ceased, I left the case and did not see her until the 25th of June, two weeks later. At this date the carbuncle was practically well, and the patient had been up and riding about the country for several days. All fever, pain, inflammation, etc., had entirely disappeared, and a silver dollar could have covered the small healthy ulcer remaining.

Now, there is nothing much in the mere recital of the foregoing case, except the principle established by the treatment pursued. For the past fifteen years I have been treating carbuncle by the acid injection plan, and I can unhesitatingly pronounce the process to be as near a sure and speedy cure for this dreadful malady as can be found in any text book if we except the knife as a means of cure. But unlike the knife, the acid produces comparatively no pain, and almost anyone can employ it in such cases if supplied with the proper equipment; to wit: the acid itself and an ordinary hypodermic syringe.

I usually add to ten minims of pure carbolic acid as many drops each of alcohol and glycerine, and have then as much of the injecting fluid as would be needed to cure the largest sized carbuncle. One grain of cocaine might be added to the above to insure freedom from pain in its administration, but this is hardly necessary as the carbolic acid itself soon acts as a local anæsthetic, and the little smarting that attends its use only lasts about a minute.

An ordinary hypodermic syringe is generally employed to inject this fluid with, though a Heaton hernia needle is preferable on account of being supplied with a blunted point. Of the foregoing mixture twenty minims should be injected right and left through the tumor, care being used to throw the fluid out towards the inflamed periphery until all portions of the carbuncle have been reached. Any excess of fluid which may ooze back through the sinuses should be picked up with clean blotting paper, and after every such injection a soft pad of absorbent cotton should be bandaged down upon the growth. Usually one of the injections will suffice, but occasionally it may be found necessary to repeat the operation in the course of forty-eight hours, should the first not be sufficient to allay the inflammation.

My attention was first called to the effects of carbolic acid upon carbuncle in 1878, when I saw a case delirious and nearly dead from the action of this terrible disorder, which I cured in a few weeks by the acid treatment. Many other cases fell in my hands shortly afterwards, all of which made excellent recoveries under the same treatment. So that in October, 1885, believing that I had established a principle in this direction, I brought the subject before the Galveston Medical Club in an article which was soon after published in *Daniel's Texas Medical Journal*, and which received many favorable notices from other medical publications.

However, the older methods are still in vogue by many surgeons, and the knife and curette are almost as busy to-day upon carbuncle, much to the horror of the victims, as they were twenty years ago.

Carbolic acid is speedy, safe and cer-

*Chief Medical Officer and Surgeon to St. Mary's Hospital.

tain, as well as a painless agent in controlling these morbid productions, and I am surprised that its employment is not more universally advocated by the profession than it is. Carbuncle is a disease attended by a specific, or rather by a peculiar form of inflammation, an inflammation that resembles erysipelas in its external manifestations, and its tendency is decidedly towards not only the death of the parts affected, but towards the death of the patient himself.

It has little or no respect for the *vis medicatrix naturae* and if not molested by surgery will destroy the life of the sufferer in two or three weeks. Many excellent citizens of this state have fallen victims to its ravages in the last few years, whose lives might easily have been saved had the acid treatment been resorted to at almost any stage of the patient's disease, and it is just to prevent similar occurrences in the future that I have been induced to bring this method of treatment before the public again.

Carbolic acid immediately destroys the peculiar inflammation or rather the cause of this peculiar inflammation which attends carbuncle. Rarely is it necessary to repeat the injection method if the first was administered properly, as was done in the case of Mrs. S., referred to, so that a physician can actually conquer one of these pathological monsters in ten minutes, or less time, and return to his office feeling confident that his enemy will give him no more trouble.

It is true that some care and nursing will be required in the retrograde stage of carbuncle-poulticing, strapping and silver applications will probably be required to expedite healing, but the specific nature of the sore having been destroyed by the acid, we have left only a simple, healthy ulcer to look after for a few days, instead of a malignant and tormenting affection.

## RAILROAD SURGERY.*

W. MURRAY WEIDMAN, M. D., Reading.

Through the courtesy of your presiding officer the honor of presenting the customary "Address in Surgery" devolves upon me. It must be conceded that the multiplicity of journals, in which the various plans of treatment in hospitals and private practice are reviewed, by an army of earnest workers, whilst shaping opinion, has a tendency to confuse the judgment of the busy practitioner remote from medical centers. This accumulation of diverse ideas would have occasioned your writer much embarrassment had he not been able to avail himself of the resolution of 1871, which permits, restriction of the subject to certain problems "in surgery," a privilege also accepted by his predecessors, many of whom were more highly favored by being reared within the walls of medical colleges and surrounded by hospitals and laboratories. Nevertheless, with much diffidence the task is undertaken in the endeavor to gratify friends who have requested the paper to be practical, thus realizing that the subject presented must be especially intended for those who, like the author, belong to to the class remote from the medical centers, but not without the hope of recalling some experiences which in the practice of all have proven to be efficient and certain means of relieving suffering humanity, especially in injuries incident to employees on railways.

The advances toward perfection, in our science, are not of such rapidity as to be marked by annual strides. Remedies and plans of treatment presented plausibly by conscientious advocates are frequently held in abeyance only to be discarded by the test of time. The principles governing the treatment of accidents are the same whether applied in hospital or elsewhere. The technique, which ought to be the same, is dependent upon the armamentarium and the conveniences of application. Hence the occasional visitor to the medical ampitheatre is often apparently much more interested in the preparations and arrangements than in the dexterity of the operator or subject presented, which are an expression of an endeavor to condense into

* Address in Surgery before Pennsylvania State Medical Society, 1893.

the emergency bag, (to be used under adverse surroundings,) all the essentials of improved surgery as exhibited in the professor's arena.

Many of you have have frequently been called, at all times, to accidents of a certain class, and fully realize under what conditions patients are found, how difficult and almost impossible the application of asepsis. For example the patient is an employee of a workshop or railroad, perhaps even a worse subject, some one who has stolen passage on the railroad. No nurses are near to make the necessary preparation of patient or operation; no blankets or vessels of hot water provided to keep the body warm; no towels steeped in antiseptic solutions to surround and protect the wound from pollution; the clothing soiled with dust and grease, often soaked with blood, rain or perspiration. The assistants are fellow workmen, willing to aid, but like the injured person, their hands are covered with grime and their clothing in little or no better condition. The ampitheatre is Nature's own, or if perchance under shelter, it is only for temporary use, hastily arranged and ill adapted. There is neither time, opportunity nor ability to bathe the injured, considered so essential prior to operations in hospital practice. No attention can be given to the bowels, and the stomach is often loaded with undigested food. Time cannot be lost, the news has spread that an accident has happened and the curious crowd is gathering not only to noxiously impregnate the surrounding air and render it more stifling, but to interfere with the work of the surgeon and his assistants. Added to these discomforts are the patient's bodily pain, mental anguish and the consciousness that loss of time will entail suffering to dear ones at home. The loss of sleep, fatigue, and excessive heat or cold, frequently enhance the difficulties. Fortunately the encouraging words of the surgeon can greatly allay anxiety—the administration of an anodyne or the anæsthetic produce temporary unconsciousness. Happily the establishment of small hospitals, in many towns, through the magnanimity of state and private charity, has of late years done much to improve the service, and formation of relief associations to ameliorate the sufferings of the injured and the wants of those dependent upon wages or salary, has lessened another adverse influence.

### HEMORRHAGE.

In the long list of accidents, there is no condition that demands more prompt relief than hemorrhage. No scene is more appalling than the sight of blood gushing in torrents from an open wound; none occasions more anxiety; none taxes the ingenuity, tests the readiness or tries the courage of the surgeon to a greater degree. Of course, the oozing from arterioles and venules, when not spontaneously arrested, can be easily controlled by pressure, exposure to air or by the application of ice or hot water. It rarely ends fatally unless complicated by a hemorrhagic diathesis. Likewise in venous hemorrhage, care must be taken, no matter what measures are employed, to stay the waste, not to obstruct the return of blood to the heart, bearing in mind that position will aid materially in its arrest. It is the arterial flow, that scarlet fluid, escaping in jets, not in a continuous stream, sometimes projected to the ceiling or across a room, that is never stayed by change of position, that causes horror and dismay, that invites, produces and prolongs shock. Many of you, I know, have heard the agonizing cry of the wounded when the nerve is pressed upon, have noticed the turgescence of the veins about the seat of constriction, have seen the anxious countenance, the ghastly pallor, the dilated pupils, the sick stomach, the profuse perspiration preceding syncope, have tried to satisfy the demand for water to quench the thirst, often the direct result of loss of blood and the misapplied garotte, the tourniquet or the elastic constrictor of Professor von Esmarch. Until the police, the trainmen, and the laity are taught that it is wrong to use such appliances above or below the wound, but that they should be directly over the wound or along the course of the bleeding vessel, that pressure will be made against a bone; so long the surgeon must expect interference with union by first intention, if no more serious trouble. Prof. von Esmarch says he has known constriction with his elastic bandage to be maintained seventeen (17) hours unaccompanied by any bad complications or results. It has been demonstrated that such constriction for two

hours and a half has been followed "by an unfavorable influence on the karyokinetic process in the tissues when deprived of blood so long." Prof. Senn at the annual convention of the National Association of Railway Surgeons in 1892, after speaking of the advantages and disadvantages of the elastric constriction announced the following conclusions:

"1st. The use of the elastic bandage to secure bloodless condition of limb should be discarded, as compression of the parts affected may produce mechanically dissemination of malignant tumors and microbic diseases.

2d. A bloodless condition should be secured by elevation of limb prior to constriction.

3d. Constriction should be made with sufficient force to interrupt at once both the arterial and venous circulation.

4th. Prevent venous stasis by constricting quickly, beginning pressure on the side of the limb supplied with the principal blood vessels.

5th. Linear or too firm constriction should be avoided, as they are liable to give rise to muscular injury, temporary or permanent paralysis.

6th. Elastic constriction of a limb for hemastatic purposes should be diffused over an annular space not less than two inches in width, and can be made with least danger of injuring important structures by a broad elastic constrictor made for this purpose or an elastic bandage.

7th. Circular constriction of a limb should be made if possible, at a point where the large nerve trunks are well protected by overlying muscles, and if this cannot be done on account of site of operation, a thick compress of gauze should be interposed between the constrictor and the limb.

8th. The vitality of tissues when excluded from the circulation is endangered by prolonging the ischemic condition for three or four hours and gangrene may take place if constriction is continued for a longer time.

9th. The process of karyokinesis in tissues deprived of circulation by elastric constriction is unfavorably affected if constriction is continued for more than two hours."

In February last, Prof. von Esmarch unwilling that the principle of his invention, viz: elastic compression, which astonished Billroth and received the commendation of Simon, von Langenbeck and many others, should be descredited; protested against the condemnation of Prof. Senn, who had said it was "not only useless but injurious" as follows. "I have remarked in the beginning that firm elastic compression in cases of suppurative affections is dangerous and advised in such cases to elevate the extremity for a short time before applying constriction and had subsequently no ill result. The same applies to soft malignant tumors, but I do not think it justifiable to abandon elastic compression entirely for these reasons alone, as there are still a sufficient number of cases left to which compression would be unaccompanied by any risks and would certainly be far superior to simple elevation, among which are the following.

1. Operations for necrosis and bone abscesses.
2. Osteotomies.
3. Operation for pseudo arthrosis.
4. Operation for reposition of old luxations.
5. Extirpations of fibroma, lipoma, angioma, osteoma, neuroma, etc.
6. Plastic operations on cicatrices.
7. Operations for Dupuytren's finger contractions.
8. Operations for suturing nerves or tendons.
9. Operations for ligation of arteries and veins.
10. Operations for aneurism.
11. Operations for removal of foreign bodies in deep tissues.
12. Operations for resection of joints without suppuration or running fistula.
13. Operation for obliteration of joints.

The bad results which have been observed after too long constriction, necrosis of the margins of the wounds, slow healing, paralysis, etc., are only caused by unnecessarily tight constriction. The constriction which I use to render the limb temporarily bloodless, as you are well aware, is not the former hard rubber tubing with chain, which I now only use in high amputations and exarticulations of the shoulders and hip joints, but the ordinary rubber band five centimeters, two inches wide, and about one hundred and forty centimeters in length, with an ordinary hook to fasten it. The important part is that the turns over-lap each

other evenly and with equal pressure. In operations on the fore-arm it is applied high up about he middle of the arm and not close to the elbow joint. In operation on the leg the constriction is made to the middle of the thigh and not close to the knee joint, thus avoiding places where tendons and nerves lie in close proximity to the surface where the successful constriction of the parts would be interfered with."

Prof. Senn replies, I will "admit that in the operations named in your letter, elastic compression could be employed without incurring immediate risks, but I must insist that it is not necessary. I have no doubt that if the directions given in the letter concerning the use of the elastic constrictor were carried out properly, we would hear less frequently of paralysis as one of the results of two tight constriction. The fact, however, remains that not infrequently paralysis of the musculospiral nerve follows as one of the immediate consequences of constriction of the arm."

Prof. Ashhurst to prevent the capillary ooxing which follows the removal of the elastic tube, recommends "to place a tourniquet in position, but not screwed down, over the main artery of the limb, and then apply the Esmarch tube a few inches above the point at which the operation is to be performed, as soon as the principal arteries have been secured, the tourniquet plate is screwed down, and the tube removed." In this way time is afforded the vessels that may have been di'ated by the paralysis of the vaso motor nerves to regain their normal tone. Prof. von Esmarch's plan is to secure the bleeding vessels, and with deep sutures close the wound.

Prof. Agnew had discarded the use of the elastic bandage, except in special amputations, on account of the time lost in staying the blood from the distended vessels after the removal of the tube and the excessive number of ligatures required. For years the writer in ordinary operations, has depended upon the elevation of the limb, an elastic constrictor two and half inches wide and one yard long, wound round the limb to embrace at least four inches, and its ends secured by means of large hemastatic forceps, in preference to a knot or hook and chain. In amputations involving the hip and shoulders, he has depended upon digital pressure and the hemostatic forceps, in accordance with the advice of Liston, who said he would "trust to a not very efficient assistant rather than put on a tourniquet," as he believed much more blood was lost from the use of the tourniquet than without it.

Anesthesia, the elastic bandage and asepticism have emboldened the surgeon to invade cavities of the body heretofore sacred, to incise and remove entire organs or portions thereof, to open joints, to suture bones, tendons and nerves, to take greater risks, in the endeavor to restore the functions of the body or a mangled limb to usefulness. Conservatism has its limits, and no matter how desirable or tempting the practice is, there remains but one course, to do that which was once considered an act of rashness, haste or brutality, but now is good surgery and an act of true humanity, as there are constantly accidents occurring which demand prompt and immediate amputation. Delay or conservating treatment in these cases is hazardous, encourages pyemia, erysipelas, tetanus, death. We need only refer to the results, as reported by Bullingham, a sequence of the order of Bilguer, who said "to cut off a limb, after a bad wound, what is it but to add wound to wound, to heap new pains upon a disordered system"—who whilst surgeon in chief of the Prussian Army "forbade amputation in any case and boasted that no surgeon had amputated a single limb. During his term 6,618 soldiers were wounded, one half of those who had a gun shot fracture of the extremities died, and of the remainder more than one-half were left in a state totally unfit for any kind of employment, civil and military. We submit to your judgment how many lives would have been saved had more prompt, more radical treatment been pursued.

### AMPUTATION, PRIMARY OR SECONDARY.

The question still remains unsettled, when shall amputation follow injury? Shall it be immediate, primary or secondary? It is stated that Duchesne in 1625, first recommended that the operation "should be performed before the inflammation and other constitutional symptoms shall have supervened." About 1692, Surgeon Wiseman declared himself in favor of primary amputation,

especially in injuries below the knee. Hennan laid down the maxim which Le Dran, in 1737, had promulgated, that "whenever there is plainly a necessity for losing a limb the sooner it is done the better." Pott says "there are many cases," and there ever will be, "where the patient's life is much more put to hazard in an attempt to save a limb than by operation for removing it. It is better for a patient to live with three limbs" or less "than die with four." Prof. S. D. Gross in speaking of railway accidents says they "are extremely liable, if an attempt be made to save the limb, to be followed by the worst results;—often the mischief is deep seated and involves muscles, tendons, aponeuroses, vessels, nerves, bones and joints, the limb is hopelessly injured and will require removal." Prof. Agnew says "persons occasionally recover from wounds of the most extensive and apparently hopeless character, without operation it is true, but such very exceptional cases are not to influence the judgment of the surgeon when deciding upon the propriety of an amputation in any given case." Military statistics amply sustain the practice of immediate amputation. Larrey admits that "a great number of soldiers were lost, although operated upon within the first twenty-four hours, yet the operation had been made too late." During the Crimean War "the success attending primary operations was two-thirds greater than in secondary among French troops," and that among the English troops did not materially differ. At Sebastapol, one-half of the primary amputations performed upon the Russians proved successful, and two-thirds of the secondary ones were fatal. Equally significant are the statistics of the War of the Rebellion, according to Dr. Otis, "who says there were 5,273 cases of amputation in the continuity of the arm for gun-shot injuries whose results were obtained. Of which number 3,259 were primary operations, with 602 deaths, a mortality of 18.4 per cent, 411 were secondary amputations, followed by 114 deaths or 27.7 per cent., 902 were intermediary operations, with 302 deaths or 33.4 per cent." So decided are these figures, that Prof. Agnew concludes "the only condition, justifying delay, when a limb has been doomed to amputation, is shock."

But why delay? Does not hesitation increase the risks from erysipelas, tetanus pyemia, pneumonia, vescical affections and gangrene of the stump? Are the sufferings of the victims diminished? Can the transportation to hospital or home, in a jolting car or over a rough road, be better born with a mutilated limb, dangling in shreds, and covered with dirt and gravel, mixed with gore, no matter how well supported or protected? Will the dangers from absorption of noxious fluids be diminished by such delay? Will the mind of the sufferer, on discovery that the mangled pulpified mass has not been removed, be any easier? The removal of a toe or a finger is done without questioning the amount of shock. In compound fractures of either extremity, the indications are and the practice is, to at once reduce the fracture and maintain the bones in proper position. In depressed fractures of the skull do we not, as soon as the symptoms of compression or paralysis appear, at once elevate the bone and remove the cause of disturbance. In neither case do we delay on account of shock. Why not fulfil the indications when amputation is as obligatory, as promptly demanded? Can the removal of the offendings, unless, cumbersome mass be more objectionable? Why wait for days, weeks, to do what is demanded promptly, and immediately demanded? Can we not under the blessings of modern science care for the stump, better than for the magled parts? Will not the duration of shock be shortened by prompt removal? Why wait until the victim has recovered, only to pass through the same nervous depression? Can we not with the aid of hypodermic injections of ether, whiskey, atropine, strychnia or nitroglycerine maintain the heart's action steady, sufficiently long, to remove the objectionable mass, then surround the patient with appliances favorable to a speedy and safe recovery.

The writer has been frequently summoned to attend persons injured on the railroad in his neighborhood, often reaching the scene of accident within half an hour. His emergency bag, on the outside of which are strapped two tin trays, is always ready and packed. It contains two rubber aprons, two porcelain dishes, a few towels, a newspaper, two cans of Squibbs' ether each one quarter pound, a

cake of soap, (recently a bottle of etherial soap (4 oz) has been substituted), a razor, a fountain syringe (2 qts) with hard rubber stop cock, 1 oz. glass syringe, 50 tablets of mercuric chloride, a bottle of carbolic acid (4 oz), 1 yd. of iodoform, carbolic, boracic and bichloride gauze in tin boxes, one fourth pound of absorbent cotton, one-half dozen sponges, rubber drainage tubes of various sizes, white and black silk, cat gut in hermetical tubes, 4 oz. whiskey, 1 doz. bandages of different lengths, pins, 4 oz. of peroxide of hydrogen, 2 elastic constrictors, 1 pepper box filled with iodoform and boracic acid powder, needles and a needle holder. The instruments and medicines are carried in separate cases. Thus equipped he has always felt ready for any single emergency.

Simple inspection will show how desperate would be any attempts to save a mangled limb. Sometimes the unbroken skin does not even show the extent of destruction. In these cases unless other parts of the body have been injured or delirium exists, not the result of drink, little time is required in preparation to remove the limb.

In giving ether the writer uses a cone, and after a few minutes entrusts the management thereof to an assistant, with instructions to withdraw the cone as soon as there is a cough or difficult breathing, sure signals of danger, which must be heeded. By observance of this law he has never had a death follow the administration of an anæsthetic and rarely has been obliged to administer hypodermic injections to maintain the heart's action. He emphatically protests against the advice sometimes given to patients to take deep and strong respirations, thus inflating the lungs with air, prior to the inhalation of an anæsthetic, far better is it to advise such inspirations after the cone is placed over the mouth and nose.

The use of medicated solutions, which formerly were so freely used for flushing wounds, have not been regarded as essential by the writer who rarely uses any of them if hot water is obtainable, which is only used to arrest oozing or to insure cleanliness. Irrigation was discontinued from no fear of poisoning, but on account of the impossibility of drying the parts, and failure to make this thorough, favors suppuration. The soft condition of the nails, the dyspepsia and loss of teeth, described by Prof. Albert of Viena, which he thought might be attributed to an extensive use of sublimate solutions has never been noticed, a brittleness of the nails and a fissured condition of the fingers of the surgeon and nurses has, however, been observed after the free use of such solutions.

Drainage has likewise been used less freely in incised wounds, and only those of absorbable material, when the flaps have been made through suspicious tissue. Retention of tubes or tents for sixty or twenty-four hour favors fistulous tracks, and prevents union by first intention. Dry dressings have always been preferred, and with gauzes freshly prepared, unless in cases where drainage is required. In either method they are not disturbed unless a persistent rise in temperature, 102° Fah. is noted ; or an offensive odor accompanied by swelling and pain is detected. The wounds are closed with sterilized gut or silk, the latter preferred. The line of incision is protected with powdered iodoform and boracic acid, and six or eight layers of gauze covered with absorbent cotton, all held in place by a bandage. After which the patient is removed to his home or hospital, and a full dose of morphia completes the treatment.

What has been said in regard to immediate amputations, where a single limb requires removal, has been found to hold good in double amputation and would be recommended in cases requiring any more serious mutilation. On four different occasions the writer has been obliged to amputate both legs, above the knee in two cases ; one recovery and one death in each class. The death in the first division ought not to be credited to the operation. The man, who had been injured whilst stealing his way from New York City at night, had his legs crushed by " the bumpers," requiring immediate amputation. He had progressed for ten days without a single discouraging symptom, when it was felt the patient could be assured of his ultimate recovery and was so told. From that moment he refused food ; did everything in his power to irritate the wounds and in spite of artificial alimentation, died within a week from pyema.

With our improved methods of treatment the question of removal of limbs in double and triple amputations, succes-

sively or simultaneously, is not of much import, except as concerns the length of time necessary for the patient to be under the influence of anesthesia. If performed seriatim, the cutting and ligitation of arteries should be done quickly; the application of sutures made during recovery from the anesthetic. Such has been the experience of the writer. It has been the means of saving lives; of giving to employees painless stumps, to which could be readily applied an artificial leg or peg; of preventing shock; in some instances of cutting short its existence.

"Ad extremos morbos extrema remedia exquisite optima."

## ADDRESS IN MEDICINE.*

S. W. LATTA, M. D., OF PHILADELPHIA.

If I needed any excuse for the departure I will make in my remarks on this occasion, or a precedent for not adhering to the strict letter of the By-Laws of this learned Society, I could find both in the language of my distinguished predecessor at Harrisburg one year ago when he said that "the spirit of the by- laws need not be violated by not literally portraying the progress of pathology and therapeutics during the past year." What I shall present, may, I trust, be of equal benefit to us all as members of the medical profession.

There are so many errors which have inadvertently, as it were, and insidiously, crept into the practice of medicine, that I propose, on this occasion, speaking of them somewhat at length and in detail.

The lamented ex-President of this Society, the late Professor David Hayes Agnew, our revered friend and the preceptor of many of us, once told the speaker that no physician was qualified to take up a special branch of his profession until after an experience of at least ten years in general practice. On this, as on every subject relating in any was to his profession, Dr. Agnew's views were sound, as being the exponents of a broad mind and the result of matured thought. Nothing has so great a tendency to broaden the mind and the man as the general practice of medicine. It makes him self-reliant, thoughtful, charitable, careful of the feelings of others.

The confidence reposed in him; the family secrets necessarily entrusted to him; the advice sought from him; the reverence paid to him; the anxious attention given to his opinions—all tendto broaden and deepen his character and fit him for any sphere of life.

Without the preliminary training thus acquired, the specialist is too apt to be narrow in his views. He has to do with but one small part of the many-sided whole which constitutes the practice of medicine.

While we admit the necessity, nay, the desirability of specialities and specialists, we deplore the tendency of young graduates to rush into them without the experience only to be gained in the general practice of the profession. The relation between general conditions and special diseases being so intimate as regards cause and effect, the cure of the special naturally following the alleviation of the general condition, makes it important that the specialist should have served his apprenticeship as a general practitioner before taking up the burdens of the special branch to which he may have a predilection, to insure his ultimate success in his chosen specialty

A specialist who has never engaged in general practice lacks experience in the general systematic disturbances which may account for the special condition, and of which it is but one, and it may be the least, important result.

With some, so marked is this lack of, shall we say, experience? that it is quite common for them to relegate the patient to the general practitioner with a query as to what constitutes the general ailment, if so be a general ailment is recognized.

Again, specialists who have not this general knowledge are prone to see nothing but the special condition and entirely to overlook the more important

* Read before Pennsylvania State Medical Society, 1893.

matter of the general character of the disturbance.

The study of the action of drugs and experience in their application to diseased conditions, is the ultima Thule of every physician. This is the summit and perfection of our art. It is for this we are physicians. To minister to diseased bodies and minds; to aid their restoration to health are objects we seek in the practice of medicine, and if errors are committed in these, he who is guilty of them is not that successful practitioner which one and all seek to be.

The growing tendency for a great many years has been to entrust the preparation of all drugs to the pharmacist.

The physician sees his patient and writes his orders in the shape of a prescription which the druggist fills. Whether he accurately compounds the prescription or not, we have no means of knowing. That he makes serious mistakes, we sometimes learn to our infinite regret and sorrow. This custom has led to many errors, one, not the least, being the temptation to write long and intricate prescriptions wherein the action of the many ingredients must of necessity produce more or less antagonism, if not incompatability and entirely nullify the action sought.

There is before me as I write a prescription containing twenty-two ingredients! What a great man that physician must have been in the eyes of the unfortunate patient! That he had such a knowledge of the armametarium of his art, at his command as to be able to fire twenty-two barrels at once! And how grave the malady where such a powerful weapon was needed!!

The habit of substitution on the part of some pharmacists is a confirmed one. The first time it is doubtless practiced with hesitation, but habit makes bold, and while he may have the drug called for, in it may be an unopened package, the temptation possibly fostered by haste and convenience, leads him again to indulge it. The character and condition of the medicine prescribed are also unknown to the prescriber, and it frequently happens that inferior quality renders inert the physiological action intended.

These are good and valid reasons against the present mode of procedure, but there are others yet stronger. The other and better plan is for the physician to carry and dispense his own remedies. It is urged as an objection against this plan that it is beneath the dignity of a physician to dispense his own medicine. Nothing which insures to the benefit of suffering humanity can lessen our dignity. Besides our fathers did it; surely their dignity did not suffer in consequence. Truly, we were well endowed had we the dignity and influence enjoyed by our fore-fathers. Can anything which tends to make the physician more successful in curing disease be neglected by him?

Again, it is urged that the busy practitioner has not the time to dispense the drugs required for each of his many cases. Surely no one can be too busy to do what is best for his patients.

The practice of hurriedly giving attention to patients, or anything which fosters and encourages the habit, works to the detriment of the physician as well as the patient. Grave errors result therefrom. Mistakes in diagnosis are apt to creep in and consequent injury to patients, and it seems to me that whatever shall lead to a more careful and thorough investigation of each case must of necessity be for the benefit of both physician and patient; to the one, in the feeling of duty conscientiously and properly performed; to the other, in the beneficient action resultant upon the best medical application known to scientific medicine.

Again, in these days when medicines can be obtained from manufacturing chemists in such forms as to be easily carried and dispensed, it should be no great hardship for the physician to provide and dispense them.

Tablets, triturates, capsules, and pills occupy but small space, their cost is not great and by the use of them the benefits to patients are incalculable.

The dangers and drawbacks from polypharmacy, shot-gun prescribing, will be greatly lessened also, and the physiological action of the drugs more likely to be obtained, while the patient will run much less risk of being over-dosed, and cures will not result from carrying a prescription, unfilled, in the patient's pocket.

Further, the patient has his medicine before the physician has left his side and any dangers which might accrue from delay are avoided. Many long days of suffering may be prevented by promptly

giving remedies, which could not be accomplished if the patient had to await the sweet will and pleasure of the autocratic pharmacist, who may also be at some distance, in the country districts several miles.

Much expense is also saved to the family, with little cost to you, as the patient will be given only what will be needed until your next visit.

The physician also will be likely to exercise greater care in prescribing remedies if on each visit he is required to furnish that which will be needed until his return to the bedside of the patient, and if a change of remedies is indicated by change in symptom, he will be more likely to make such than if a partially used 8 oz. mixture stares him in the face as so often happens.

The sick room will not look like a drug shop on a small scale, with its array of mixtures, tinctures, pill-boxes, and what not, and the patient's friends will not feel that they are "long" on a quantity of drugs, literally drugs on the market on which there is but small chance to realize. The baneful practice of "renewing" a prescription by presenting the bottle with its numbered label, without orders from the physician, would also be a thing of the past.

Office patients would be more likely to pay cash, as there would be no further expense entailed until the next visit to your office, and while they, under the present plan, may have to save their money to pay the druggist, this will now be paid the doctor, and patients, I refer to those in poorer circumstances, will feel when the physician gives them their medicine, that they have received something which calls for immediate payment. To this fact is largely due the success of our Homœopathic friends among a certain class.

The prescribing largely of the compressed tablets, capsules and such like pharmaceutical product also furnishes the medicine in a more convenient and palatable form, and will in time do away with the great dread of disagreeable nostrums with which our revered forefathers nauseated their long-suffering clients.

The universal practice of prescription writing, is in my opinion largely answerable for the large increase in counter-prescribing and in the consumption of patent medicines. The patient is aware that if he consults a physician he will send him to a drug store for his medicine. He thinks to save the Doctor's fee and goes direct to the druggist for advice and medicine, the former of which will cost him nothing.

The almost universal practice of charlatans and quacks in advertising free consultations with charges for medicine only is one of the leading factors in obtaining patients.

If by dispensing our own medicines we can lessen these two growing evils, is it not our duty to do so? Do not understand me to propose free consultations—far from it; but only to urge the desirability of combining the consultation and medicine fee in one.

Another growing evil of our day is the increased attendance upon free dispensaries where both advice and frequently medicines are given gratis. People well able to pay are constant patrons, and many cases really requiring no treatment constantly infest these places because it costs them nothing. All beneficiaries of these admirable charities should be required to furnish proper certificates before being received and treated as such.

The lamentable ignorance of many practitioners regarding hygienic laws is to be regretted. I take it to be the duty of every physician when called upon to attend a case of either zymotic or telluric disease, to use every effort to ascertain the cause. It goes without saying that a cause must exist. Every physician should be a plumber in theory,—should understand the best means of disposing of offal and drainage; should be *au fait* on the subject of ventilation; should be an expert in the matter of proper food supply and the way to detect adulterations or harmful changes in its composition. He should know what constitutes a proper water supply; the dangers of water contamination and be prepared to suggest the remedies.

The proper disinfectation of houses and rooms occupied by cases of contagious diseases should be as familiar to him as the prescribing of quinine for malarial fevers; and yet how many of us give the proper attention to these most important matters. As physicians we are responsible not only for the cure of diseases but

also for their prevention, and unless we are good scientific hygienists we will miserably fail in successfully performing this part of our work. The time may come when we will be employed, as is the physician in China, not to cure disease but to prevent it. The growing tendency of the age is toward preventive medicines, and woe betide that physician who is ignorant of the laws of health and how to preserve it!

We daily hear of learned members of our profession who are successful in "breaking up" a threatened attack of typhoid fever or some other equally serious complaint. They tell the patient that they have been sent for just in the nick of time, else he had doubtless died of the seizure. However, that he is safe now as they feel sure they can break up the threatened attack. How ridiculous and how prone is such conduct to bring reproach upon our noble profession. These record breakers should be frowned down and the people given to understand that we do not all countenance fraud.

I deplore the growing tendency to deceive the laity by giving them to understand their condition is serious, when it is not, and that marvelous cures have been brought about when nothing serious ailed the patient.

Untoward results may, and doubtless do, result from such unnecessary alarms. I cannot silently approve of or be a party to such deliberate falsifying, which is done for the purpose of gaining self-glory, and believe it to be as bad or worse than publicly advertising for patients. It can only be done for notoriety, for the purpose of enlarging the clientele of the doer, but done by false representations. I believe it proper and right candidly to state to the intelligent patient the true condition of his physical state, except in rare contingencies. I also believe such candor often aids the cure; and I deprecate any deceit, particularly that which may lead to the continued illness or a prolongation of the disability of a patient, by reason of premediated misstatement of facts.

The object I had in view in the foregoing remarks, which may seem severe, was the desire to elevate to a higher plane the practice of medicine, to give publicity to my condemnation of what seem to me improper and unbecoming practices;—to express my sense of the duties devolving upon us as physicians; to accept and adopt all means looking toward the successful practice of our art; to urge the necessity of doing anything and everything which may in the slightest degree assist us in becoming more successful in combating disease and relieving the many ills to which poor humanity is the heir.

Let us, therefore, be enthusiastic but honest practitioners, truthful to our patients, true to ourselves, and diligent in fulfilling the grave responsibilities which rest upon us as conservators of the public health.

## ADDRESS IN OBSTETRICS.*

THOS. D. DUNN, M. D., West Chester.

A resolution adopted by this Society in 1871 provides for an annual address in obstetrics, reviewing the progress during the preceding year of this branch and collateral sciences.

When your President extended this honor to me, I was ignorant of this by-law, and when it was first discovered, the difficulty of complying with the spirit and the letter of the law in the time allotted seemed well-nigh insurmountable; a hasty examination of previous addresses in obstetrics showed many deviations from this rule. This is not mentioned in a spirit of criticism, but to induce a charitable consideration of the present attempt.

The frequent publication of reviews of medical progress, annuals and compendiums, makes this work unnecessary. To review the contributions to obstetrical literature is no easy task; and from the vast amount of material it is difficult or impossible to always decide which is really valuable, and which time and the light of experience will prove worthless. Old things that have long been weighed in the balance and found wanting are frequently resuscitated by new aspirants to fame, clothed in new form and presented as novelties. Occasionally, how-

* Read before Penn. State Medical Society, 1893.

ever, one that has been relegated to oblivion is brought forward and under the light of a new age, and under new conditions proves to be golden grain and not chaff. The time alloted will scarcely permit the mention of all the good things that have been written, but it affords an opportuuity to refer to a few important subjects.

During the past year considerable attention has been given to the use of anesthetics in labor.

No argument would seem necessary at this time to justify their use to relieve the mental and physical suffering of childbirth, were there not a goodly number of physicians who do not use them at all, or only in instrumental deliveries. Within a year I have heard a general practitioner who has had a fair practice, and who is a member of the State and National Societies, announce to a body of medical men that he never used anesthetics, even in forceps delivery.

But the prejudice of the past has happily largely disappeared, and the superstition that once existed, that labor being a physiological process, and the suffering therefore natural, should not be interfered with, has fortunately been abandoned.

Whenever there is pain, whether the result of physiological functions, diseased conditions or surgical procedures, humanity demands its relief. The aversion to the use of anesthetics which is often caused by fear of ill-effects is usually easily removed, though this fear is too frequently encouraged by the timid and unskillful attendant. It is true anesthetics sometimes have a depressing effect and may increase the tendency to postpartum hemorrhage, but these untoward results depend largely on the manner in which they are employed. In surgical operations, if profound anesthesia is induced, the tendency to both primary and secondary hemorrhage is increased, and there may be marked disturbance of respiration and circulation. These dangers exist also in the use of anesthetics in labor, but they should not be condemned in the latter class of cases and approved in the former. That they are improperly given by some should not interfere with their administration by the skillful. Except in cases of version, abdominal section, symphysiotomy, and rare forceps deliveries, complete anesthesia is seldom required.

For their intelligent use it is necessary to recall for a moment a few facts in the physiology of labor. The nervous supply of the uterus is such that its rythmical contractions are carried on independent of volition—the source of this supply being the ganglionic centers of the spinal cord. Their action may, however, be inhibited by the higher cerebral centers, as, for example, in the suspension or irregularity of uterine pains as the result of fright, the sudden arrival of an unwelcome medical attendant or nurse, shock or exhaustion from prolonged suffering. During the nervous excitement of conscious pain, uterine contraction is often feeble or may cease altogether, and it is not uncommon to see dilation arrested for hours.

Who has not repeatedly seen a few whiffs of chloroform quiet this excitement and strong regular uterine contraction follow and labor be brought to a speedy and successful termination? Here the cerebral excitement inhibits the nervous mechanism of uterine contractions, and this excitement the anesthetic removes. The spinal centres are then free to restore the rhythmical contraction of the uterus.

The relaxation of an anesthetic also lessens the tendency to injury of cervix and perineum. By relieving the violence of the suffering by partial anesthesia, the voluntary assistance of the mother is under the control of the physician—a condition necessary to the successful management of delivery.

Dr. Edward P. Davis, in *Philadelphia Polyclinic* for April, in an article on "Anesthetics in the Treatment of Labor," thus strongly states their advantages:

"In prolonged and difficult labor, some of the greatest dangers which threaten the mother and child may be lessened by the skillful use of anesthetics.

"The element of shock may be thus lessened or prevented. Exhaustion of the uterine muscles, the greatest predisposition to hemorrhage, is far less frequent when anesthetics are employed. Injurious pressure upon the child less often occurs when the forces of labor are regulated and controlled by partial anesthesia. The facility afforded in diagnosis and operation to the physician from the use of an anes-

thetic is a fact too familiar to require discussion."

A comparative study of anesthetic agents which are employed in parturition has been made by Chaigneau (*Journal de Medicine de Paris*, Apr. 19, 1892). He believes antipyrin has given but moderate results. Chloral is often uncertain, unless used in large doses, which frequently cause gastro-intestinal irritation. Lord (*Omaha Clinic*, Oct. '92) advises it in all cases where an anesthetic is required, except where there is great cardiac weakness. It frequently relieves the teasing pains in the first stage of labor, and prevents the exhaustion of the mother.

Cocaine has been employed successfully by Jaenne in 5 per cent. solution applied by a tampon to cervix and vaginal cul de sac. Doléris uses a 4 per cent. cocaine ointment with much advantage. Auvard recommends the injection of 15 to 20 minims of a 5 per cent. solution of cocaine in each *labium majus* a few minutes before delivery, which greatly lessens the suffering of this stage.

Chloroform, as stated by Parish in his review (Sajous, *Annual of the Universal Medical Sciences*, 1892), seems to be the favorite anesthetic of most writers, and he expresses his surprise, in view of its many advantages and few dangers, that it is not used more frequently. He believes the condition of syncope is the only contra-indication for its use.

Acute or chronic disease of lungs, heart or kidneys ought not to deter the careful physician from its judicious employment. Under the prudent use of chloroform the rapid, feeble, nervous pulse of the person in labor will become steady and full. It is indicated in cases where the pains are severe and badly borne, where the uterine contractions are irregular, where there is marked rigidity of the cervix and firm resistance of the perineum.

Its tendency is to lessen rather than increase the danger of post-partum hemorrhage—a direct result of diminishing uterine exhaustion, and it has been my experience, as well as that of others, that it is not uncommon to see what was considered a complicated labor speedily converted into a normal one by its use.

For my part I resort to partial anesthesia by chloroform in a majority of my parturient cases, and I have yet to see any ill-effects from its use. Our duty in a mother's hour of trouble and peril is not alone confined to safe delivery of the child —human suffering demands relief.

In operative procedures, as in difficult forceps deliveries, post-partum hemorrhage where interference is required, abdominal section and symphysiotomy, ether is doubtlessly safer and better. A careful discrimination should be made between ether and chloroform in cases requiring complete anesthesia.

The past year will long be remembered in the history of obstetrics on accout of the introduction of symphysiotomy in America. At the last meeting of the American Gynecogical Society, Dr. Harris, of Philadelphia, read a paper calling the attention of the physicians of this country to the marvelous results of this operation in Italy. This article made such an impression that the operation became at once popular, and many successful cases have been reported. A brief history of the operation may not be out of place here. It was first performed in France on the wife of a French soldier by Jean Rene Sigault in 1777. It received a favorable consideration in Italy, but was rejected in Germany and England.

From this period to 1858, Dr. Harris collected seventy cases, with a death rate to mothers of 37 per cent., and to children of 67 per cent. In spite of this high mortality to both mothers and children, Professor Morrisani, of Naples, revived the operation, and from 1866 to 1880 he and other Italian obstetricians performed the operation fifty times, reducing the mortality of mothers to 20 per cent. and children to 18 per cent. From 1881 to 1885 fifty-two cases were operated upon, with the fearful mortality to mothers of 44 per cent., but the loss to children was reduced to 13.5 per cent. The genius of Morrisani was not doubted by these discouraging figures. He worked quietly and persistently in perfecting the operation under antiseptic management, and in Naples, from January, 1886 to January, 1892, it was performed in twenty-eight cases with the lost of but one mother (from causes not traumatic) and three children.

During this period the success of the Sänger Cæsarian method in other countries caused it to supplant symphysiotomy, but the knowledge of the good work done in Naples, after January 1, 1892, spread to

France, Germany, Russia, Ireland and America. Since then we have been on the crest of a symthysiotomy wave. Repeatedly had Morrisani written on the subject previous to this, but he preached to deaf ears outside of Italy; he must now, however, realize the highest fulfilment of his hopes. During 1892 the operation was performed at least 40 times with the loss of but one mother.

The following is the list of the American operators in their chronological order: Jewett, of Brooklyn, Sept. 30; Hirst, of Philadeiphia, Oct. 3; Broomall, of Philadelphia; Michael, of Baltimore; Noble, of Philadelphia; Springle, of Montreal; McKennan, of Paris, Ill.; Garrigues, of New York; Duff, of Pittsburgh; Lusk, Coe and Grands, of New York.

Thus, since Sept. 29, 1892, the operation has been performed 11 times in the United States and once in Canada, saving all the mothers and nine children.

During the year 1892 (*Annales de Gynecologie et Obstetrique*, Jan., 1893), Pinard performed symphysiotomy 8 times, and his associates in the Baudelocque Clinic of Paris 5 times—13 cases in all. All the women recovered and the pelvis in each instance united solidly, and they made perfect recoveries in every particular, while only three of the children perished. It is the consensus of opinion that the operation should be limited to flat pelves with a conjugate diameter between $2\frac{3}{4}$ and $3\frac{1}{2}$ inches, *i. e.*, a pelvis not so highly contracted that a living fetus cannot be delivered after the operation by version, or, preferably, the forceps. If the diameter be less than $2\frac{3}{4}$ inches, Cæsarian section should be selected, and version and the judicious use of forceps resorted to when between $3\frac{1}{2}$ inches and the normal conjugate diameter.

Careful pelvimetry before labor, and the estimation of the size of the child's head *in utero* in its relation to the pelvis, will enable the obstetrician to make up his mind as to the course of labor, and decide what operation ought to be elected in each individual case to save maternal and fetal exhaustion.

Leopold (*Centrallblatt fur Gynakologie*, No. 30, '92) gives the following directions for the operation:

"The mother is placed upon a table with buttocks projecting. Two assistants hold the legs, slightly separated, with one hand below the knee, while the other presses the trochanters together. An incision is made through the skin from the upper border of the sypmphysis to 1 cm. above the clitoris. The soft parts are separated down to the joint; the insertion of the recti muscles is transversely divided only so far that the left index finger may be introduced behind the symphysis. The finger is inserted to the ligamentum arcuatum inferior and the joint separated by a blunt-pointed bistoury. The pubic bones immediately separate to 3 cm., and by careful separation of the knees and transmitted pressure on the trochanters to 7 cm., at any rate, so far apart that the large head immediately enters the superior strait and is easily and rapidly delivered by high forceps operation. The assistants immediately press the mons veneris so tightly together that the pubic bones touch. They are then united by silver wire sutures or strong silk along the soft parts and the wound closed. A strong and very broad binder, provided with buckles, holds the pelvis together for the next three weeks and is daily tightened. It is not necessary to separate the ligamentum arcuatum, nor, indeed, to cut through the entire symphysis, as after half or three-quarters separation the upper ends are 3 cms. apart. In pelves, in which, following rachitis the direction of the pubic symphysis and the upper sacral vertebra converge upward, also where the principal hindrance to the entrance of the head is the projection inward of the upper segment of the symphysis, it is necessary to open only so wide as the individual case demands."

The future of symphysiotomy is full of hope. Its advantages are not confined alone to the great reduction in mortality of mother and child. The profession is becoming painfully aware of the army of idiots, epileptics and cranks, the result of injuries to the brain of prolonged and difficult forceps deliveries. Cerebral injuries are almost as frequent after version in the extraction of the head.

Dr. J. M. Taylor (*Annals of Gynecology and Pediatry*, 1892) has called attention to the importance of this subject in an "Inquiry as to the Causes Producing Cerebral Injuries in the New Born." Embryotomy has ceased to be a justfiable procedure on a living child. The

induction of premature labor in cases of contracted pelvis must be greatly restricted. Even with strict antisepsis, statistics show for this operation a death rate to mothers of 5.3 per cent., and of 45.3 per cent. to infants. This operation can therefore stand no comparison with symphysiotomy, which ought to have practically no mortality to mothers, and has less than 10 per cent. to children.

Present indications are that the integrity of the symphysis pubis is completely restored in three or four weeks after the operation. The remote effects of injury to the birth-canal in symphysiotomy are much less than in version and difficult forceps deliveries. The brilliant results of the Porro and Sanger Cæsarian operations have been confined to the most skillful hands in the large cities and hospital clinics. Their advantages have thus been denied the majority of these unfortunate cases. In choice between section and embryotomy the vast majority of rural practitioners will choose the latter. The simplicity and ease with which symphysiotomy is performed will extend its advantages to villages and country districts. Thus many women and children will be saved by physicians who would not undertake a section.

For these results one man and one country deserve all praise—Morrisani, of Italy, gave us symphysiotomy.

So much has been said and written during the past ten years in favor of antiseptic midwifery, it would seem unnecessary to introduce the subject here, but as long as there is puerperal infection in private and hospital practice, and there are physicians who fail to give their patients the protection of rational antisepsis, this war against sepsis must go on. There must be no indifference in the matter, and even at the risk of reaching the point of "mental saturation" to many, no argument should be withheld while any man refuses to be convinced.

In hospital practice, since the introduction of antisepsis, there has invariably been an enormous decrease in morbidity and mortality.

Dr. Joseph Price has had over 1200 cases of labor at Preston Retreat, Philadelphia without a death from any cause. Before delivery the patient is thoroughly washed with soap and water and given a single 1–2000 bichloride vaginal douche, which is repeated once on delivery of placenta.

Garrigues (*Med. News,* Nov. 26, '92) gives the following results of the new treatment in the New York Maternity Hospital:

During the nine years previous to its introduction (1875–1883), 3504 women were confined, 146 of whom died, *i. e.*, 4.17 per cent., and of these 17 or 17.17 per cent. succumbed to sepsis. During the last month of this period the total mortality reached even 20 per cent., and that from infection 15.69. During the first three months after the change—from Oct. 1, 1883 to Jan. 1, 1884—there were 102 deliveries without a single death, and from Jan. 1 1884 to Jan. 1, 1891, 3170 deliveries with 30 deaths, 7 cases succumbing to sepsis. Thus the total mortality has been reduced to between one-fourth and one-fifth of what it formerly was, it now being less than 1 per cent., and that from sepsis less than one-fifth per cent.

The records of the Sloane Maternity (Dr. Jas. W. McLane, *Am. Jour. Obstet.*, 1891) show that in 1000 cases, 6 cases were lost and only 1 from sepsis, or one-tenth of 1 per cent.

Braun (Herzfeld, *Central. f. Gynäk,* 1890), at the Vienna Clinic, had 1004 consecutive cases with only 2 deaths. Many other hospital statistics might be cited, showing equally satisfactory results.

The value of internal disinfection before delivery has been debated much in the past few years, especially in Germany. Some have carried antiseptic measures to such extremes that they become burdensome and even injurious.

Thirty deaths from poisoning have been reported, the result of the immoderate use of bichloride injections. It is natural that this announcement should be followed by a reaction against internal disinfection.

One French writer (quoted by Garrigues, *loc. cit.*) went so far in his antiseptic zeal as to require bichloride injections (1 to 2000) twice a day, beginning four weeks before delivery. The week previous to confinement they were given every other day and the vagina tamponed with iodoform gauze. The injections were also continued after delivery.

Mermann (*Central f. Gynäk.*, 1892) has had 700 cases with but one death,

and that from rupture of the uterus. He conducts labors without internal disinfection, but his practice is to make no internal examination in uncomplicated cases.

Leopold, Glöekner, Keller and others think that internal disinfection before delivery increases both mortality and morbidity.

Frommell (*Deut. Med. Woch.*, 1892, No. 10), on the other hand, believes in an internal injection of bichloride as a prophylaxis of puerperal disease. He finds no increase of sepsis from frequent examinations by students in his clinic when this precaution is taken. When he relied on external disinfection, puerperal infection occurred.

Hoffmier (*Deut. Med. Woch.*, 1891) advocates the disinfection of the birth-canal before delivery, and shows from comparison of the statisties of Wurzburg clinic with those of others that it is not a source of danger to the mother, but, on the other hand, even with the examinations of students, it diminishes puerperal disease.

Steffeck (*Zeitschrift f. Geburt. Gynäkol.* Bund XX, Heft 2) has made a bacteriological study of the secretions of the vaginal canal in 29 healthy women before delivery. The secretions were examined, cultures made and both injected in animals. Twelve cases gave positive results, abscesses followed in seven, and in five general puerperal infection. The germ most frequently found was the staphylococcus pyogenus albus. He concludes that this germ, as well as streptococci, may cause puerperal infection which should be considered an auto-infection, and strongly urges the prophylactic douche before delivery.

Garrigues (*loc. cit.*) very pertinently denounces the extremes of these views, and advocates a single vaginal injection before delivery, to wash out germs and dirt.

Antiseptic treatment of puerperal women can be made both simple and effective. The patient should have a hot bath and the external genitals thoroughly washed and disinfected. There should be a single vaginal injection before delivery of simple boiled or borated water, or a solution of bichloride, 1 to 2000, or a 1 to 2 per cent. creolin solution. The physician and nurse should wash hands (also arms in case of section) thoroughly with the indispensible nail-brush, and disinfect with 1 to 2000 bichloride solution. If lubricants are used (which is seldom necessary), they should be aseptic. After the birth of the child, in normal cases, the vaginal tract should not be examined and disinfection is not required. If portions of placenta remain, they must be removed, and, as in cases of instrumental delivery or version, the birth canal and sometimes the uterus itself should be flushed with an antiseptic douche. Instruments should be boiled or rendered antiseptic by strong solutions.

Probably among the uncleanly, in private as well as in hospital practice, disinfection of napkins or pads would be safer.

The benefits of antisepsis in hospitals have been repeatedly demonstrated beyond all doubt. While there may be slight variation in detail, it is practically the same in all. Every woman, in private practice, about to become a mother, should be surrounded by the same safeguards the poorest and filthiest have in hospitals. Too frequently the woman who has all the comforts and skill money can secure, is not protected by the physician from the poison that lurks in the private dwelling. The treatment is simple and materials inexpensive, and it is a crime to receive compensation for our work, as well as a violation of the sacred though unwritten pledge of the physician, if these precautions are neglected.

In conclusion, I wish to add a few pertinent quotations from that classical essay on the Contagiousness of Puerperal Fever, by Dr. Oliver Wendell Holmes.

It was read before the Boston Society for Medical Improvement, and printed in the *New England Quarterly Journal of Medicine and Surgery* for April, 1843, reprinted with additions in 1855, and appears in his "Medical Essays." It should be read by every physician who enters the sacredness of the lying-in chamber.

"For my part I had rather rescue one mother from being poisoned by the attendant, than claim to have saved forty out of fifty patients to whom I had carried the disease.

"God forbid that any member of the profession, to which she trusts her life, doubly precious at that eventful period, should hazard it negligently, unadvisedly or selfishly.

"Let the men who mould opinions look to it; if there is any voluntary blindness, any interested oversight, any culpable negligence, even, in such a matter, and the facts shall reach the public ear, the pestilence carrier of the lying-in chamber must look to God for pardon, for man will never forgive him."

I beg to offer to this Society the following preamble and resolution, which I sincerely hope may be adopted:

"WHEREAS, Experience, both in this country and abroad, shows that by strict antiseptic measures the mortality in lying-in hospital may be reduced to a minimum, and

"WHEREAS, Deaths due to child-birth are yet too common in private practice;

"*Resolved*, That, in the opinion of the Medical Society of the State of Pennsylvania, it is the duty of every physician practicing midwifery to, as far as possible, surround such cases in private practice with the same safeguards as are being used in hospitals."[1]

---

### Short Articles Preferable in Live Medical Journals and Medical Societies.

If busy members of the profession realized how easy it is to make note of important features in important cases while engaged in their round of work, and then to arrive at conclusions regarding same, there would be more of it done, and as a result therefrom short, terse contributions might easily often be made to medical journals and to medical societies. An immense amount of time is often wasted by the writer in approaching his subject. Unnecessary side-issues are brought in and valuable points are frequently lost in a world of words. Too many men in preparing a paper feel that it is their duty to give the views of all who have preceeded them, and then in a labored way to present their own. Far better would it be if they would adopt the rule in their contributions of making one point at least, and making that point so distinct, definite and permanent as to enable one to hang his hat on it.

The chairman in the section on Diseases of Children of the New York Academy of Medicine, Dr. Wm. P. Northrup, recently (*N. Y. Med. Jl.*) sent to members of his section suggestions for the preparation of papers as follows:

1. "Hippocrates and Galen may be passed with slight notice, as they have been dead for some time and their opinions are somewhat obsolete.

2. Scratch out the formal introduction, and begin where the subject-matter really begins.

3. Condense the body of the paper.

4. End the paper where the subject-matter ends, making its action like that of the piston syringe—begin, spatter, stop."

Yes, let every contributor begin promptly. Let him spatter as little as possible and then stop promptly. Some philosopher once said that "he is a fortunate man who knows when to retire from the salon and the world." He might well have said: He also is a fortunate man who, when contributing an article to a medical journal or a medical society, knows how to begin and knows when to stop.—*Med. Mirror.*

---

### A Peaceable Race.

The Japanese manner of settling quarrels is original. When one man has offended another, the injured party gives notice that he is angry by drawing in the sand before the door of the offender a circle with a straight line across it, indicating that his affection, which would have been eternal, has been cut in two. Friends of both parties then shut them up. They parley awhile, then pretend to be born again, prattle as little children, and finally as men become reconciled and embrace. Should one be refractory and refuse to be conciliated, he is ostracized by the community so effectually that he is soon brought to terms. It is just possible that our enlightened citizens might consider this method better than knock-down arguments and certainly much cheaper than going to law.—*Harper's Bazar.*

---

### A Sure Preventive.

Bridget. "Phawt's t' privint me tellin' yure mother on yer, Tommy Barker, shtealin' caake loike a thafe?"

Tommy. "Honor, Bridget. Didn't you kmow there was honor among thieves? —*Harper's Weekly.*

[1] This preamble and resolutions are nearly identical with those presented by Dr. Henry J. Garrigues, at the section on Obstetrics and Gynecology of the New York Academy of Medicine Oct. 27, 1892, and unanimously adopted.

# The Medical and Surgical Reporter

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 = 18 = 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, SEPTEMBER 16TH, 1893.

## EDITORIAL.

### INJUDICIOUS HOUSE QUARANTINE.

That there has been advance in medicine, surgery and hygiene in recent years can not be denied. The advance has on the whole been direct and continuous, but at times it has been interrupted, and sometimes there has been retrogression. This is especially true of the present practice, in the supposed interest of public sanitation, of domestic quarantine of houses and their occupants on account of the presence of one or more cases of diphtheria or scarlet fever or similar disease. Aside from its enforcement in the over-crowded "poor districts" of great cities, the practice is often ill-judged, often worse than useless, sometimes injurious and not rarely cruel and barbarous.

There seems to be a growing tendency to exaggerate the danger of contagion in such cases. The risk of infection from personal contact is very small. That nurses and attendants on such cases rarely acquire the disease is a matter of history. Unless the association is close and continuous, as by occupying the same room or bed, with absence of ventilation, it is rarely seen. The evidence that these diseases are conveyed by fomites or carried by attendants on their clothing or otherwise to outsiders is not such as to satisfy scientific requirements. Anyone of much personal experience must have seen how seldom these diseases spread, even to other members of the family, if care in separation and ventilation is insisted on, and personally we have never known a case where the physician carried them from his patient to other families. It appears that the present notion of the communicability of these diseases, which seems to obtain with many physicians, does not come from study and reflection upon past experience, but from theoretical fancies about pathogenic germs and *a priori* generalizations, reasoning from the microscope and culture medium to the sick-bed instead of the reverse.

The tendency seems to be developing into something like a sanitary panic, and the consequences cannot but be deplorable.

The health authorities in many states have been empowered by law to require physicians to report all contagious diseases to local boards of health, and penalties are attached for neglecting to make such report, and this report is required immediately, often before a correct diagnosis can possibly be made. This is a direct bid to report as a contagious case every sore throat, red rash, or fever. Such a course may be forced upon the honest practitioner as a precaution against annoying prosecutions, and it may be gladly resorted to by the less scrupulous as an advantageous business operation, for every sickness reported as contagious and cured redounds to the credit of the attending physician, and deaths are condoned by the name of the disease. That the reporting of these diseases to local boards of health might be of some use in enabling the cause of infection to be located we do not deny, but we feel like protesting against the practice of sending a so-called health officer—generally a police officer in buttons—to visit the houses where such cases are reported and placard them as pest houses, giving orders that no one shall be admitted, forbidding the family from going out for business, health or pleasure, and giving instructions as to the sanitation of such houses. This is absolutely unnecessary and cruel. It is barbarous to the sick, and their relatives and friends, and impertinent and discourteous to the attending physician. It causes great and needless fright to the families and alarm to the neighborhood, has a tendency to aggravate the disease in the sick, and renders other members of the family more likely to contract it from the depressing effect of fear. The practical imprisonment of all the residents of the house, cutting them off from exercise in the open air and from all the cheerful associations of friends, is an encroachment on personal rights which nothing but the extremist could justify. Its tendency is to cultivate in the community a feeling of timidity, cowardice and selfishness, which is to be deprecated, and it indirectly teaches the profession and the people to look for the causes of these diseases where they do not exist. The sewer inlets, cess-pools, kitchen drains and foul, close cellars are to be shunned—not unfortunate fellow citizens.

Contagia differ in their nature. It is fairly well proven that those of cholera and typhoid fever are respectively distinct and specific germs which are ingested in contaminated food and drink. Here the alimentary tract is to be guarded. Those of diphtheria and scarlet fever seem toarise from accumulated animal or vegetable matter in process of decay, favored by lack of light and by still air, and they commonly effect their contact with persons by germs floating in the air. If the air is in rapid motion they are blown away and become harmless. Here cleanliness and ventilation are paramount. These are quite different from the contagium of small-pox. This is personal, its habitat is man, and possibly the cow. No account of cleanliness in ourselves and our surroundings is of avail against this disease, and it may unquestionably be carried by fomites. But it is effectually prevented by vaccination and that is our only safe reliance, not house-quarantine which is necessarily uncertain. In guarding the community from contagious diseases we must not forget the natural history of the particular contagion in question.

Cholera is exotic, and its germs may be excluded by certain measures of national quarantine, but, when once imported, the food and drink are the things to be guarded, not persons. Home quarantining of individuals will not effect so much. Scarlet fever, diphtheria and typhoid fever are indigenous. These diseases will always develop when the conditions are favorable. Here the essentials are cleanliness, sun light and ventilation rather than house quarantine.

It is not wise to whip the stream to catch pigeons nor to beat the bush for trout. Before we press measures of sanitation that are grievous and burdensome to the community, let us at least be sure that we are right. Let us guard ourselves and the community from panic, and by no means become victims of sanitary hysteria.

## TRANSLATIONS.

### APPENDICITIS AND THEIR COMPLICATIONS FROM A SURGICAL STANDPOINT.*

The author, K. G. Lennander, reports 34 operative cases which were operated upon by him and his assistants between the fall of 1888 and summer of 1892. There was but one death which took place 5 weeks after the operation; cause pyæmia, caused by a small gangrenous portion of the intestine which had been overlooked during the operation. In 3 cases laparotomy with extirpation of the vermiform appendix was performed, in which diffuse peritonitis existed. In three other patients suffering from appendicitis, there were found 2 or more incapsulated intra peritoneal abscesses which were opened and drained, in only 2 of these was it possible to remove the vermiform appendix; of these 3 it was found necessary to make incisions through the vaginal vault and the colon. In 12 cases abscesses were found in the iliac fossa and in the lumbar region, an opening was made; 3 times extirpation of the appendix. Of the 9 remaining 3 have had returns and there was 1 death, which has been reported at the beginning. In 7 cases laparotomy and amputation of the ulcerated and gangrenous appendix; operation performed 40 to 60 hours after the begining of the attack, with the exception of 2, in which the attack had lasted 4 days in one and in the other 9 days.

Pelvic abscesses were present in three cases, one having discharged through the vagina and two through the large intestine. Amputation of the vermiform appendix was performed five times during the free intervals. Chronic appendicitis was diagnosed in one case and operation revealed an abscess of the appendix, while the adhesions between the ilio cæcal and the anterior wall of the abdomen were dense, these were released during the operation. As far as the author has been able to follow his cases the patients are all well; three still remaining under observation.

During this time two patients died of gangrenous appendicitis who had refused operation; one had an inoperable carcinoma at the head of the colon, and the other was supposed to be suffering from a perforating ulcer of the stomach, and this presumably giving rise to the existing perintonitis.

Etiologically the author speaks first of foreign bodies or fecal calculi, the latter according to his idea forming in the appendix (not in the cæcum as Talamon teaches); further he believes in the possibility of a retention of the secretions, aided by the swelling of the mucous membrane and particularly assisted by a bend or constriction of the bowel. The author has observed this in one case in which he operated and later was able to palpate it in two cases before the operation.

The primary stercoral typhlitis was observed by the author in several cases and is there inclined to take the opposite view of Sahli.

Severe repeated attacks of appendicitis in which the pathological changes have been entirely confined to the vermiform process, and suppurative peritonitis in which there were only catarrhal changes of an unperforated vermiform appendix were also seen by the author. Lennander prefers the rectal amd vaginal examination. He has in several cases found the difference in temperature above the normal between the axillary and the rectal methods, which Madalung has found to be pathognomonic of suppuration in the

*Translated for THE MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

lower portion of the abdomen or the pelvis. Lannander does not operate during the interval between the attacks, only at the express wish of the patient. He then opens down, releases all the adhesions which seems to him to be of pathological origin, and then invaginates the stump into the cæcum. If diffuse peritonitis is present a section is unavoidable, indeed strictly indicated; if the pus formed has become incapsulated he tries, if possible, to avoid opening into the free abdominal cavity and prefers to drain and with the aid of antiseptics feels certain that this method is less dangerous than to allow an unopened, undrained pus pocket to remain in the pelvic cavity. His incisions are usually in the median line or latterly. If the latter he directs his incision along the motor nerve in order to avoid hernia.

During the operation the author uses a warm solution of sodium chloride (sometimes twenty to thirty litres). If at all possible the appendix is removed and generally no intestinal suture is made, but closes the opening by the application of Peans forceps which are left in the wound, drainage of iodoform gauze is used between the loops of small intestines, Keiths glass drain is placed. The accumulative fluid is aspirated during the twenty-four hours, once in three hours, or oftener if necessary. Narcosis, at first chloroform by drops and later ether. The after treatment consists in small doses of morphia for the existing pain. To avoid symptoms of ileus the stomach and intestines are washed out; nourishment is given as early as possible and in rapidly increasing doses. If necessary warm enamata (500 to 600 g.) is given to check the thirst, once or twice daily.

The continuance of even slight symptoms of ileus is an indication, to the mind of the author, of more abscess or of fecal accumulations. As a rational treatment in cases of relapses of peri typhlitis Lennander recommends careful massage but only in the doctor's hands; this may also be the best method by which he will be able to gain thorough knowledge of the anatomical conditions present.—*Upsala Läkarenfören.*

# ABSTRACTS.

## CLINICAL THERMOMETERS.

The following abstract from the Report (1892-93) of the Managers of the Observatory of Yale University, is of material interest to the profession and will warn those physicians who put their trust in instruments of precision:

It continues to be true that only a small percentage of the instruments sold are sent to us for certification. It is presumably true, also, that those which are sent here for certification, by the manufacturers, are carefully selected, and, therefore, far more reliable than the avarage of those sold without certification. Nevertheless we are sometimes compelled to reject 25, 50 and even 75 per cent. of those sent us. As a rule, these are not rejected without receiving double the care and time required by the large majority of those to which certificates are accorded.

When there is taken into account the large percentage which the cost of certification adds to the manufacturer's prices, it is not to be wondered at that when he has succeeded in continuously producing, for a season, instruments with few and uniform corrections, he should point to these conditions as justifying his customers in accepting his instruments without other certification than his own. In those cases of this sort which have come under our observation, we have noticed that apparently the workman, when he no longer has occasion to expect his work to be traversed by a disinterested authority, soon relaxes his efforts at an accuracy which is hardly yet fully appreciated by the ultimate consumer, and his instruments, when they come to us from his customers, are not quite up to the standard maintained when he was continuously, or at short intervals, submitting them to such test: possibly he is not making due allowance for his changing standards.

It may not be out of place to again invite the attention of our puplic to some points in the construction of registering clinical thermometers, which are frequently overlooked by makers and users of these instruments.

In those forms where the index is a short column of mercury—one-third to one-half an inch long—separated from the rest of the mercury by a small bubble of air, the index is often lost by being thrown down into the bulb, the bubble escaping into the attenuated atmosphere of the tube, and when the index is restored the separating bubble is not likely to be of the same dimentions, and the temperature indications will not be the same as with the former bubble. The difference in the lengths of the tube occupied by the old and new bubbles will account, approximately for the differences in the readings. The bubble should always be as small as is consistent with its function of separating the columns of mercury. The tube should extend sufficiently beyond the maximum readings required, that the compressed atmosphere at the top of the tube may not force back the index, when the support of the mercury in the bulb is withdrawn by cooling.

In those forms where the "Indestructible index" is maintained by a "trap" near the bulb, the various constructions of this trap may, at certain points, cause the index to drop irregularly when the mercury below the trap has contracted, or may occasion a motion of the index by jumps: in fact in most of the reliable instruments of this form, it is merely a question of the number of jumps taken by the index in rising one degree;—most of those in which the index rises perfectly smoothly and without jumps, will justify the suspicion that the index will drop, as soon as the mercury in the bulb contracts from the trap. While the index is rising freely the motion may appear continuous, but when the index is within a degree or two of coming to rest and rising slowly, the jumps may, usually, easily be counted. Our recent practice has been that, when these jumps average 0°.1 or less, and the readings repeat themselves, throughout, within the prescribed limit of accuracy, the usual certificate is given: if the jumps avarage more than 0°.1 and less than $\frac{1}{5}$°,—the readings repeating themselves as before, we modify the certificate by making the limit of accuracy "0°.2" on the same certificate form: and when the jumps average more than $\frac{1}{5}$°, we give no certificate. The process of producing the trap leaves its walls in a somewhat unstable condition, so that moderate concussions may cause particles of glass to separate, which particles, acting as a plug, may temporarily sustain the index, which, when the plug is dislodged may drop. The contraction here is so small, and the particles of glass so fine, that it is not always easy to detect them. The same dropping of the index may be due to the varying effect of air in the trap.

---

### One of Bismarck's Habits.

Once when Bismarck was a cavalry officer he was standing with some other officers on a bridge over a lake. As he was about to give an order his groom, Hildebrand, rode one of the horses to water close by the bridge. Suddenly the horse lost footing, and Hildebrand, clinging to the animal disappeared with it in the water. Before the other officers could collect their senses Bismarck had cast off his sword and his uniform and had thrown himself in the lake to save his servant. By good fortune he seized him, but the man clung to him so closely in his death agony that he had to dive before he could loose himself from him. Bismarck rose to the surface, raising his servant with him, and brought him safe to land in an unconscious condition. The next day the servant was as well as ever. But the little town that had wittnessed the brave rescue was in great commotion. They petitioned the superintendent, who obtained for the young officers the medallion "for rescue from danger." And now on great occasions, the well known Prussian safety medal may be seen beside the proudest stars in Christendom on the breast of the famous creator of united Germany. Bismarck, it is said, is prouder of his first medal than of all the rest put together. One day in the plenitude of Bismarck's power a noble minister approached the premier, and with a tinge of satire asked him the meaning of this modest decoration. He at once replied: "I am in the habit sometimes of saving life." The diplomatist lowered his eyes before the look which accompanied Bismarck's lightly spoken words—*Chicago Herald.*

# THE LIBRARY TABLE.

## BOOK REVIEWS.

*An American Text Book of Surgery for Practitioners and Students.* Edited by William W. Keen, M. D., and J. William White, M. D. Pp. 1209. Philadelphia: W. B. Saunders, 1892.

This volume represents the work of thirteen American Surgeons, all well known professors in as many as twelve medical schools of this country.

One great objection to this work is the fact that its articles remain unsigned; yet those familiar with the recent contributions of a number of these authors to the medical press cannot help but be impressed how closely they resemble the text, in fact some of them tally line for line with a number of reprints distributed to the profession.

"As may be expected," says Mr. Frederick Treves, of London, in his review of this work, "the quality of the different articles varies considerably, and the fullness with which the individual subjects are discussed is not to be measured by one standard. Undue prominence has been given to certain surgical matters, while others of less immediate interest, but of no less importance, receive too scanty a treatment."

The book opens with an article on Surgical Bacteriology which, while interesting to most readers, is of little use to the practicing surgeon or physician. It is not sufficiently comprehensive and thorough. For instance, the text states that dry heat of 212°F. will in 1½ hours kill bacteria. This would be misleading to the ordinary medical reader as it implies that dry heat 212° F. will produce sterility, whereas, should the mass contain spores, which fact no practitioner can determine, the spores would remain in full vigor and reproduce this kind when introduced into a favorable soil. Again in speaking of mercurial chloride: Koch is quoted to the effect that corrosive sublimate 1 to 1,000, destroys the most powerful organisms in a few minutes. This in the abstract may be correct; however, it will not do for practical surgery where albumins are generally present. This was long ago demonstrated by Professor La Place and others; the fact being that albumen will break up the mercurial chloride into its constituant parts and thereby destroy its germicidal qualities to the degree necessary to satisfy the albumen present; therefore for practical work the solution must be used much stronger than 1 to 1,000, or tartaric acid added as suggested by Dr. La Place.

The attempt to teach the practitioner how to stain bacteria is another instance of want of thoroughness to make it of use to either the student or surgeon.

The statement is made on p. 677: "Vomiting takes place as frequently in wounds of the abdominal parietes and in simple penetrating wounds as when the viscera have been injured." This is an error as vomiting is quite common in visceral injuries, but is exceptional in penetrating wounds without visceral injuries, *e. g.* A gunshot wound entering the abdomen, penetrating it and lodging in the dorsal muscles, nausea is absent; but a wound of the stomach or ilium is followed by the most persistent nausea. Again, on p. 680, under the head of "Preparation of the Patient," attention is called to the use of "atropia and morphia;" this in the hands of the most advanced operators has been strongly condemned as it gives very often a restless and uncontrollable patient. On p. 681, in discussing length and point of incision a long incision is again recommended, this incision is not practiced by expert operators; it increases the shock, loss of blood, exposure of viscera and undue manipulation to control of viscera; it necessitates the crowding of the ether to profound anæsthesia which should be avoided in all such cases. On p. 683, the use of sponges taken from chemical solutions is harmful; in fact the sponging of the peritoneal cavity at all does mischief. On p. 704, "Puncture of the Intestine" here is recommended, a procedure that is now considered not only uncertain—but a dangerous practice in the hands of anyone. On p. 789, "Ventral Hernia." This important subject does not receive the attention that it deserves; on account the number of abdominal operations in the hands of the inexperienced and careless operators ventral hernia has become very common, so much so, that a more thorough and detailed account should have been here given. The surgery of ventral hernia is new, trying and difficult.

In treating of diseases of the eye about as little has been written as could be written for the enlightment of the "Medical Profession and Medical Student of America" when it is remembered that but comparatively few general practitioners would undertake the operations for glaucoma, cataract, and the various plastic operations upon the eyelids. We cannot do an injustice to the solitary chapter of forty pages devoted to the subject if we quote its opening words. "In a brief article on the surgery of the eye it will be impossible to include its anatomy, physiology, pathology, therapeutics and the means of examination by instruments or glasses, or to do more than mention the causes that render a resort to surgical procedure necessary, and describe the various operations themselves. All reference to the diseases of the choroid and retina are omitted, as they belong rather to ophthalmic medicine than to surgery." This may be technically correct, but we might have reasonably expected a description of the ophthalmoscope and the method of using it. Such knowledge is certainly requisite for the modern ophthalmic surgeon. It seems somewhat inconsistent that reference should be made at some length to "paralytic squint due to disease involving the nerve centers or trunks or rheumatism." What does it avail a student to be told that

glaucoma occurs especially in the hypermetropic, and that at the sclerotic ring we may "find with the ophthalmoscope" "the characteristic *cupping* of the papilla" when he receives no hint either as to the nature of hypermetrophia, or the use of the ophthalmoscope? It would seem as if all helpful reference to instruments of precision for diagnosis were omitted from this work, leaving the student to search elsewhere for descriptions of the laryngoscope, rhinoscope, ophthalmoscope, endoscope, etc. What information as to diseases of the eye is vouchsafed, is accurate and reliable, but it manifests haste in preparation, is curt in diction, and includes references to "astigmatism," "stenapaic slit," and "high convex cylinders" which must be utterly unintelligible and bewildering to the student. Pp. 1108, which is devoted to the statistics of eye diseases might have been more profitably utilized for a short account of the ophthalmoscope or even a brief description of the anomalies of refraction and accommodation.

Chapters VI and X are so very unsatisfactory that they had better have been omited altogether. The work contains 37 plates and 437 wood cuts. Of the wood cuts, claim is made for 52 as original. Dr. Shadd, Professor at the Howard University Medical College, Washington, D. C., calls attention in the *Medical and Surgical Observer* February, 1893, to p. 198, "Enormous sarcoma of Buttock," says that he finds a photograph of his patient "taken from a duplicate picture of the cut, without any credit given to the Freedman's Hospital where the patient was for several months under treatment, and where the true type of the disease was diagnosed." This error can readily be set right in the second edition should the demand require one, together with other claims for credit.

---

*A Manual for Boards of Health and Health Officers.* By Lewis Balch, M. D., Ph. D., Secretary State Board of Health of New York; Health Officer of Albany; Emeritus Professor of Anatomy and Professor of Medical Jurisprudence, Albany Medical College. Banks & Brothers, Albany, N. Y. Price $1.50.

The Secretary of the State Board of Health, Dr. Lewis Balch, has prepared a Manual for the use of members of local Boards of Health, Health officers and all others interested in health matters. The book is exactly what it purports to be, a practical working Manual. It defines the powers of the State and local boards, it contains directions to the local health officer, it gives examples of problems which may arise and their solution, it offers suggestions for the prevention of disease and it includes directions to be followed in times of danger from epidemics of contagious diseases which formulate the best method of stamping these out which experience has devised. It solves many legal questions in the most plain and practical way. The value of the Vital Statistics gathered by the State Board is explained and the duty of those who are required by the law to fill out the certificates, is fully defined. Blank certificates, having the questions properly answered, are given as models to be followed. Bound with the Manual is a copy of the Public Health Law to which it is designed to serve as a Commentary. The volume will be found to be of the greatest value to all who are interested in the Public Health and it will enable Boards of Health and Health Officers to be certain of their positions in their dealings either with their Municipal governments or with the people.

## MEDICINE.

### Gangrene Complicating Cholera.

Durr (*Rev. de Med.*,) first refers to the great rarity of this complication. He relates the following case in a man, aged 50, who had been suffering for some time from dyspepsia, and who was greatly afraid of cholera. On September 19th he was seized with premonitory diarrhœa, and two days later he was suffering from a typical attack of cholera. The reaction appeared on the 22nd, after which the patient, without permission, got out of bed. He was then seized with pain in the right leg, and the next day, ecchymoses appeared on it, and there was an absence of warmth and sensation. On the following morning the toes were gangrenous. On the 28th he died, the gangrene having extended nearly up to the knee, and no line of demarcation having formed. Only the leg was examined after death, and nothing was discovered besides, perhaps, some narrowing of the posterior tibial artery. The author then refers to twelve recorded cases, including another of his own. The gangrene may be dry or moist. Of the twelve, three were examples—all fatal—of moist gangrene (Mouchet), including two necropsies. In the other nine it was dry, and only two recovered. In these dry cases the arteries supplying the gangrenous area was obliterated. Thus this obstruction is constant, but there are three possible ways of explaining it: (1) embolism, (2) parietal arteritis, and (3) localized arterial spasm. Potain says that in enteric fever there is often spasm of the arteries of the limbs, but, if death occurs, the artery is found permeable. Varcot has insisted on arterial spasm in cholera; thus in one case the left pulse was imperceptible, but later it could be felt. The spasm may cease, or be the first stage of obliteration. In the author's case of gangrene in the hand, there were two distinct periods, one of spasm, and the other of oblite-

ration of the artery separated by a remission, in which the arterial pulsation could be felt. Reasoning from other infective processes, the author is inclined to think that the arterial spasm is probably secondary to an arteritis, and is not a primary condition.—*Br. Med. Jour.*

### Peptonuria in Phosphorous Poisoning.

Robitscheck (*Deut. med. Woch.*,) relates the following acute case from v. Jaksch's clinic. A girl, aged 19, took in solution the heads of five boxes of ordinary matches on November 27th. A few hours later there was vomiting and much pain in the epigastrium. On admission, (November 30th) she was apathetic, and still complained of much pain and vomiting. The conjunctivæ were slightly icteric, but the skin of normal color. Palpation over the liver and stomach regions was painful, but the liver could not be felt. The stomach was washed out with 8 litres of water, and then with a solution of copper sulphate—a method which has been used with good results in this clinic. Phosphorous was detected in the first washings. Albumen were present in the urine, and the deposit obtained by the centrifugal machine showed a few leucocytes and red blood cells. Careful examination proved the presence of abundant peptone. On December 1st, the skin and mucous membrane were yellowish. The patient was worse. There was no poikilocytosis or leucocytosis. The treatment consisted in the administration of sodium bicarbonate in large doses, potassic permanganate, and turpentine. The peptonuria was less marked. On December 2nd the liver was found to be enlarged and the icterus had increased. There was no destruction of red cells. No peptone was now present in the urine. The patient died the next day of cardiac failure. At the necropsy, the liver was found to be much enlarged, and abundant minute hemorrhages were present in the body. This case shows that peptonuria does occur in phosphorous poisoning. It differs from Maixner's observations, in which the peptonuria corresponded to the intensity of the symptoms, and gradually disappeared with recovery. Von Jaksch refers the peptonuria to the scorbutus. It is conceivable that it stands in relation to the hemorhages, and that the peptone appears as long as fresh and abundant hemorrhages occur in the body. It is important to prove the presence of peptone in the blood, but in this case the blood was only examined when the peptone was disappearing from the urine, and the biuret reaction was then doubtful.

## SURGERY.

### Massage in Muscular Rheumatism.

Graham (*Amer. Jour. Med. Sciences*, vol. cvi, No. 2, August, 1893), referring to lumbago, points out that this may arise from cold, strain, fatigue or rheumatism. Its pathology is probably coagulation of the semi-fluid contractile muscular substance, and adhesion of muscular fibrils, so that motion gives rise to partial, irregular and painful contractions. Retention of waste products occurs, the worst of these being uric acid. Recent cases of muscular rheumatism are almost invariably cured by a few massages. The same result may be brought about by rest, warmth, electricity, or the use of such drugs as salicylate of soda, though not so rapidly. Graham claims for massage five different actions, namely, mechanical, thermal, electrical, nervous, and chemical, and suggests that when a case of apparent muscular rheumatism not only does not yield but does not remain improved after a few massages, the probability is that the case is one of neuritis affecting the nerve fibres that supply the impaired muscles. This probability would be strengthened when the pain is uniform, affecting the same muscles on both sides, when it is worse at night, when at rest and warm in bed, and better when up and moving about; whereas muscular rheumatism is aggravated by motion and relieved by rest and warmth. Massage may thus be used as a means of diagnosis between muscular rheumatism and neuritis.

### Riders' Bursa.

Le Fort and Albert (*Rev. de Chir.*) report four cases of a swelling near the knee, to which they give the name of riders' hygroma. According to these surgeons, there is often developed in horseriders a subcutaneous serous bursa seated near the inner surface of the knee, which is caused by the rubbing of this part of the limb against the saddle. This serous bursa, like the normal bursæ, cannot be made out in the healthy condition by ordinary modes of investigation. It sometimes becomes inflamed and swollen as a result of irritation, and there can be no doubt that this condition may run on to suppuration, although no case of this kind has yet been recorded. The situation of this bursa varies in different subjects according to the degree of outward turning of the foot during riding. Its most common situation is over the internal condyle, the center of the sac being a little behind the centre of this surface of bone. The tumor formed by the swollen bursa is rounded or oval, and usually presents the character of an ordinary hygroma. It is quite superficial, moves freely with the skin, has no direct connection with the bone, and, except in rare instances, does not communicate with the interior of the joint. It is by no means a troublesome affection. Acute or subacute inflammation of the sac will interfere, while the attack lasts, with the movements of the knee, but afterwards this restriction will soon cease. Chronic enlargement of the bursa will not impede either flexion or extention of the leg, and, unless the swelling be very large, will not prevent the rider from mounting his horse. This variety of chronic hygroma will, it is thought, be found of frequent occurence if attention be more widely directed to the condition. The treatment recommended is that usually applied to similar swellings in other regions, the method preferred by the authors being that of puncture followed by compression.

### Electrolysis in Fibrous Ankylosis.

Gwyer (*Annals of Surgery*) draws attention to the great value of the galvanic current as a means of dissolving new-formed fibrous adhesions. The author usually uses one large flat electrode and one small sponge electrode with handle. The large electrode should be nearest the adhesions and attached to the negative pole, and the small one applied to the opposite side. Both electrodes should be wet with salt solution, and of solutions tried the best results have been obtained with a rather strong one of ammonium chloride. The current is turned on, and increased till the patient will stand no more. The older the adhesions, the greater the current necessary to dissolve them, and Gwyer believes in a strong current for a short time rather than a weak one for a longer period. The current should be applied from ten to thirty minutes at intervals of from one to five days.

### New Method of Direct Fixation of Fragments in Compound and Ununited Fractures.

Senn (*Annals of Surgery*) makes an earnest plea in favor of a more frequent recourse to direct means of fixation in the treatment of ompound a nd ununited fractures. In preference to suturing, metallic spikes and screws, or ivory cylinders and clamps, Senn prefers, as absorbable interosseus splints, hollow perforated cylinders of bone introduced into the medullary canal; these do not interfere with production of callus, and are more quickly absorbed than ivory or metal. But the safest and most efficient means of direct fixation of oblique fractures is by bone ferrule, applied in such a way as to surround both fragments. Such a circular absorbable direct splint prevents to perfection lateral and longitudinal displacement, and rotation of the limb below and angularity at the seat of fracture must be prevented by plaster-of-Paris splint. Senn has employed this method in three cases with excellent results.—*Br. Med. Jour.*

## OBSTETRICS.

### Hæmophilia and Parturition.

Wehle (*Centralbl. f. Gynak.*) opened an important discussion on that question at the May meeting of the Dresden Gynecological Society. The patient, in a case under his own observation, was a primipara, aged 33. After being for ten hours in labor at term, she had rigors; the membranes had burst one hour previously; the fœtal head lay in the first position, in the outlet. Flooding had set in. Wehle gave morphine and waited one hour, then delivered by a single traction with the forceps. The peritoneum and clitoris (slightly wounded) bled freely, and so did several abrasions. The wounds were sutured. The placenta was extracted by expression, after free flooding. Three defects were noted on its surface. Hot water was injected into the uterus. Whilst this was being done the three missing pieces of placenta were removed. Ergot was given; the uterus contracted and the flooding ceased for a while, but the small abrasions, which had been sewn up, began to bleed, and deeper sutures had to be applied. Then the flooding set in again, and the uterus was plugged with iodoform gauze. A laundress's iron, placed over the middle line where there was a gap between the recti, served well to ensure counterpressure. The vagina required firm plugging, as the sutured wounds and the tracks of the sutures bled freely. The patient was in a state of collapse. In two hours, after taking stimulants, she rallied. On the third day the vaginal tampon, and on the fourth the uterine plug, were removed. For six weeks bright-red blood occasionally trickled away, and five weeks later she was very anæmic and rather weak. In the child the stump of the cord bled, though twice ligatured. Wehle found that the patient's father had been subject to epistaxis, and died, aged 42, of cerebral hemorrhage. One of his brothers was also troubled with epistaxis. One of the patient's sisters had flooding for a whole day when 18, and severe flooding after the birth of her third child; and her nose often bled. One brother (also subject to epstaxis) was seized, when 17, with pains in the joints, and died of extensive subcutaneous hemorrhages. It further transpired that the patient herself, when 2 years old, bled freely from the genitals after a fall. When 12 she bled from the alveolus for a day after extraction of a tooth, and she had epistaxis and bleeding from the gums during her pregnancy. There was no history of syphilis or nephritis, no atony of the uterus, nor laceration of the cervix. The discussion turned on the diagnosis of hæmophilia from syphilis. Manuel saw fatal epistaxis in an infant, aged 3 days, notwithstanding careful plugging. The father had suffered from a hard sore. Meinert stated that the father was also syphilitic in a case where the stump of the cord bled for four days. Marschner recorded three labors where there was great flooding during the third stage, without any anatomical explanation. Professor Leopold attributed flooding in Marschner's ease to atheroma of the walls of the vessels in the uterine mucous membrane. When there was no hereditary history the obstetrician should not be too ready to attribute bleeding to hæmophilia. Mothers with syphilis often flooded in the third stage, and syphilitic children were subject to bleeding.

### Labor Obstructed by Ovarian Tumor.

A. F. A. King delivered a white woman, an 8-para, aged 38, in a Washington hospital, in December, 1892. She had been over five days in labor, yet was not exhausted. The perineum was distended the anus patulous, and a tumor filled the pelvic cavity so as to leave only just enough space between its anterior aspect and the symphysis to admit two fingers by which the presenting part (the face) could be felt, just beginning to enter the pel-

vic brim. The tumor was so tense that there was doubt as to its being solid or cystic. King punctured it through the rectum, believing that rectal puncture would be less liable than vaginal to infection from the lochial discharge, and that the puncture would be less obstructed by pressure of the presenting part. Ovarian fluid free from odor escaped, with increased rapidity during the pains. When the obstructing mass had disappeared the cannula was removed, and with a few more strong pains the face descended, the chin swept round to the pubes, and a dead child was born, without further aid, in about fifteen minutes. The cord, 21 inches long, was flaccid and brownish. The placenta followed, and the patient recovered. A month later she was admitted into another hospital with fever, expectoration, and dulness with moist *rales* over the right lung. The tumor reached two inches above the umbilicus, and pressed downwards in the pelvis. The right foot was œdematous, and there was tenderness, without redness, along the femoral vessels. When the patient was under examination it gave way, a profuse discharge of fœtid pus escaping from the rectum. An incision was made in the posterior vaginal wall, and a gallon of offensive pus came away. A drainage tube was inserted, and the cyst cavity irrigated for three weeks. After staying two months in hospital the patient was discharged, the cavity had completely closed, and the lung symptoms were much better.—*Am. Jour. Obstet.*

### Membranous Dysmenorrhœa and Uterine Casts.

Schonheimer (*Archiv. f. Gynak.*), in a memoir on the pathological anatomy and symptomatology of menstrual uterine casts, shows that the separation of a structure more or less like the entire endometrium in shape, is the result of chronic inflammatory changes. These changes cause the uterus to shed fibrinous structures in great quantity at the menstrual period. This phenomenon is never seen between the periods, and it gives rise to the disorder known as membranous dysmenorrhœa. Sometimes, but not necessarily, the exfoliation of membrane is accompanied by an acute local inflammatory process. Schonheimer relates two instructive cases. The first was a typical instance of membranous dysmenorrhœa. The patient was 29. The catamenia began at 17, and were painful, though regular, from the first. At 23 she married. Coitus was always painful. The left tube was slightly thickened. A fortnight after marriage she suffered from discharge, but it soon passed away. At the age of 25, and thenceforth till when she came under observation, the patient passed flat three-cornered casts at every period. Dysmenorrhœa was intense, and the patient was sterile. The membranes were purely fibrinous deposit, full of leucocytes. Here and there some uterine epithelium was seen entangled in the meshes of fibrine. The os was dilated and the uterus scraped. The scrapings consisted of true endometrium tissue, showing hyperplasia of the sub-epithelial connective tissue without any acute inflammatory changes. As is usually the case, treatment was unavailing, and the patient continues to pass casts of the uterine cavity. The second patient was 43. When a girl she was anæmic, and did not begin to mensturate till she was 20. The period was never regular till she married at the age of 26. She never had pain during the catamenial flow. She bore six children and aborted once. She showed no evidence of syphilis; all her labors were normal. After the last confinement she began to pass uterine casts at every third period. There was total absence of pain, the casts being discovered accidentally. Electricity was applied, and the curette was used; yet, just as in the cases where mensturation is painful, treatment did not alter the condition of the patient. She continues to pass clots. This case shows that pain is not an essential symptom of discharge of fibrinous membrane from the uterus, and that the phenomena in question does not necessarily entail sterility. —*Br. Med. Jour.*

## THERAPEUTICS.

### Treatment of Diphtheria.

Levy and Knopf (*Berl. klin. Woch.*) describe the treatment of this disease with papayotin (Gehe) and carbolic acid. They prepared the diphtheria poison after the method of Behring and Wernicke. When some papayotin was added to this diphtheria poison, and the mixture kept at 37° for two days, the virulence was much diminished. Thus papayotin has a weakening effect on the diphtheria poison. If papayotin were allowed to remain in contact with the living bacili without carbolic acid, the whole rapidity underwent putrefactive changes. In the treatment of cases the following preparation was used: Papayton, 10.0; ac. carbol. puriss. liquefact, 5.0; aq. destil. ad 100.0. The affected parts were gently painted every ten minutes for the first two hours, and then at intervals of every two hours afterwards, and this was continued during the night. There was rapid improvement in the local manifestations. The ice collar, abundant inhalations, and plenty of wine were used as usual. The cases of diphtheria when admitted are nearly always severe, the mild ones being kept at home. Encouraged by the good results, the authors sometimes delayed tracheotomy a little, and with satisfactory results. Of 51 cases thus treated 36 recovered, tracheotomy being performed once, and 15 died, of whom 5 were tracheotomized. Among the fatal cases there was 1 of genuine pneumonia, 1 of tuberculosis, 1 of repeated hemorrhage from the tracheotomy wound, and 3 of extensive broncho-puemonia. Among the recoveries there were 3 cases of nasal diphtheria, 13 of marked obstruction to the air passages, 2 of measles, and 1 of croupous pneumonia with naso-pharyngeal abscess. When compared with cases hitherto treated in the clinic (Strassburg), the mortality was

diminished and the number of tracheotomies lessened. Naturally the authors do not look upon this local treatment as unfailing, but the good results obtained have led them to publish them.

### Combined Effects of Morphine and Sulphonal.

Gonzales (*Arch. di Farmacol. e di Terap.*,) recognizing the good points in the action of this hypnotic, but realizing also that its effects in man are not quite so satisfactory as the results of experiments on animals would have led us to think, was led to try to reinforce its action by association with morphine, the main trouble with sulphonal being that the sleep is neither very deep nor very lasting. The subject was first investigated on frogs, with the following results. Sulphonal alone in the mean dose of 0.04 gramme causes no symptoms; save abolition of voluntary movements for some hours. Morphine alone (0.008 grammes of hydrochlorate) produces marked excitement, lasting for about an hour, the animal then returning to normal. The two drugs given in combination in the same doses caused marked and lasting narcosis, lasting for many hours. On the heart *in situ* sulphonal alone causes a slight diminution in the frequency, but increases the strength of the systole, and the amplitude of the diastole. Morphine alone only reduces the frequency. The mixture of the two drugs is without action on the frequency, but increases the force of the systole and amplitude of the diastole. Similar results were obtained in the case of the isolated heart. The results on mammals were as follows: In rabbits (doses 40 centig.) and dogs (doses 75 centig.) sulphonal produces sleep generally in half an hour from the administration, the reflexes and respiration being unaltered, and the heart beats frequent and vigorous; but the sleep is not at all profound, and in dogs is sometimes wanting. Morphine produces it in rabbits about twenty-five minutes after the injection, but the animals soon shake it off; in dogs it lasts a still shorter time. The mixture of the two drugs is perfectly successful both in dogs and rabbits. The sleep appears physiological, and lasts from seven to ten hours, and is not in any way complicated by unpleasant sequelæ; the heart and respiration are unaffected. The author finally recommends this mixture of the two drugs as an admirable and safe hypnotic, free from cardiac depressant action, and efficient even in insomnia due to neuralgia and nervous excitement.

### Intravenous Injections of Corrosive Sublimate in Cases of Cerebral Syphilis.

This mode of treatment was first introduced into use in Italy by Baccelli. Jemma (*Rif. Med.*, July 18th, 1893), recognizing the brilliant results obtained from its use by this observer, has administered sublimate in the same manner in four cases of cerebral syphilis. He regards it as particularly suitable in such a case, for it is very necessary to secure a prompt action of the drug, and impregnation of the system through the gastro-intestinal tract is too often a slow process. The drug is made up into a 1 : 1000 solution with distilled water, and a little salt and alcohol to aid solution. It is administered by injection into one of the superficial veins of the arm, generally the cephalic, using an ordinary hypodermic syringe, and taking care to sterilize both the skin and instruments. The operation is quite easy, and causes practically no pain. The dose begins at 1 c.c., being increased to 2, 3, and 4 c.c., which last is the maximum employed. Its use in the author's four cases showed the method to be rapid in action, as well as safe, if performed with due care. The maximum effects are obtained with a minimum dose, and that without any pain such as accompanies hypodermic injections. The author has also employed the injections in other conditions, but beyond establishing the practibility of the method, his observations have not yet been sufficiently numerous to allow him to draw accurate conclusions. He promises shortly to give further details of these cases.

## ARMY AND NAVY.

U. S. ARMY FROM SEPTEMBER 3, 1893, TO SEPTEMBER 9 1893.

Leave of absence for one month, is granted Major David L. Huntingdon, Surgeon U. S. Army.

Leave of absence for two months, to take effect from August 25, 1893, is granted Lieutenant Colonel Charles R. Greenleaf, Deputy Surgeon General, U. S. Army.

A board of officers to consist of Colonel Joseph C. Bailey, Assistant Surgeon General, Major Calvin DeWitt, Surgeon, and Major Henry M. Cronkhite, Surgeon, is appointed to meet at the call of the president thereof, at San Antonio, Texas, for the examination of such officers as may be ordered before it, with a view of determining their fitness for promotion.

Captain Henry S. Kilbourne, Assistant Surgeon, will report in person to Col. Joseph C. Bailey, Asst. Surg. General, president of the examining board, appointed to meet at San Antonio, Texas, for examination for promotion.

Captain Marcus E. Taylor, Assistant Surgeon, having been found by an Army retiring board, incapacitated for active service, is granted leave of absence, until further orders on account of disability.

Leave of absence for four (4) months, to take effect on or about October 25, 1893, is granted First Lieutenant Allen M. Smith, Assistant Surgeon U. S. Army.

Capt. Julian M. Cabell, Assistant Surgeon, is relieved from duty at Fort D. A. Russell, Wyoming, and ordered to Washington Barracks, D. C., for duty with the company of instruction of the Hospital Corps.

**Phenacetine-Bayer**

ANTIPYRETIC and ANALGESIC; Prompt, safe and effective in Fever, Influenza, Rheumatism, Neuralgia, Pneumonia, Cephalalgia and all forms of pain.

Phenacetine is given in doses of 2½ to 10 grains, 3 or 4 times daily. It does not depress the heart.

Phenacetine is supplied in ounces, also in tablets and pills, alone and with Salophen, Sulfonal, etc.

**Sulfonal-Bayer**

HYPNOTIC and SEDATIVE; Indicated in all the Insomnias including those of insanity and the Neuroses; Causes no nervous or gastric disturbances. Must be given as directed.

The dose of Sulfonal varies from 15 to 45 grains; It should be given an hour or two before bedtime.

Sulfonal is supplied in ounces, tablets and pills; also in tablets in combination with Phenacetine.

*Other Farbenfabriken Products:*

## ORIGINAL ARTICLES.

### PSYCHICAL DISLOCATION AND THE THEORY OF MEDIUMISM.

JOHN E. PURDON, M. D., Cullman, Ala.

As a distinguished gathering of scientific men and women form all parts of the civilized world attended the Psychical Science Congress, held at Chicago, in August, under the Chairmanship of that distinguished member of our profession, Professor Elliott Coues, M. D., of Washington, D. C., who has done so much to uphold the honor of American scholarship by his versatility, thoroughness and originality, I would like to make some remarks upon a subject which occupied to some extent the attention of one of the sections of the Congress. I refer to the physiological and pathological conditions accompanying specter-seing, which in itself, has been a fertile source of dispute whenever the hard-headed disbeliever has tried to convince the believer in the reality of ghosts that their existence is all a matter of the imagination.

We know from the investigations of Galton that many persons are possessed of the power of visualizing, that is to say, of intensifying the act of memory by such a voluntary effort as objectifies in terms of form, color and perspective some past experience of the sense of sight. But any figure presenting itself to the minds eye under such conditions of natural or acquired power, which he found to be pretty common among those to whom he addressed his enquiries, does not come under the category of such subjective beings as those to which I refer.

The well known story of Nicolai, the bookseller who was haunted by spectres until he got himself bled, when they gradually faded away, losing their color and becoming indistinct in form and ultimately vanishing never to reappear, is reasonably accounted for by the old expression "pressure of blood on the brain," the optic centres being of course those chiefly disturbed, when they would express their disapproval most naturally in their own functional language.

I have, however, had experience of cases in which mere blood pressure or, on the other hand, anæmia of the brain centres, would not be sufficient to account for the phenomena, observed. In a former paper reference was made to a young woman, a medium for the manifestation of spiritual phenomena, who was attacked with severe nose bleeding during her extraordinary exhibitions and who quite lost the power of color discrimination for a time. As I was at that time, twenty years ago, a psychical researcher on physiological lines, I followed up the subject wherever I found cases that would afford information on the subjective side, and which would be analogous to that which I fully believe had been demonstrated to me on the objective side of existence. The girl in London, twenty years ago, had the power

of projecting space realities from her nervous system as I know to be a fact; it was therefore advisable that I should try and find out as far as possible the *modus agendi*. We are now in the rational and enquiring age of spiritualism, having passed through that of negative dogmatism and *a priori* determination of possibilities; consequently a little rational gossip upon the subject of sense disturbance with a side bearing on spiritualism will not be out of place even in a purely professional journal.

In 1874, I had a patient in India who afforded me some interesting results. She had been a carpet sewer by trade before she married into the army, and the jar consequent upon her work, followed by a long railway journey to the station occupied by her husband's regiment, set up violent uterine hemorrhage, which continued to be profuse at each of her catamenial periods. She then suffered most violently from headache and at the same time the color vision was greatly disturbed on one side. Blue blindness was marked with her. I used sometimes to sit in the darkened room with her, to give her an opportunity to describe the faces she saw and the proceeding was to all intents such as I often indulged in under another name. But nothing other than subjective symptoms were ever observed.

About the same time I had under my care an older woman, who also suffered from irregularities of menstruation with violent headaches at her monthly periods, and also from achromatopsia of a periodic character. This woman was worried at times with figures standing before her mind's eye, but she, unlike the other woman, gave me good and satisfactory proof that she was a true ghost seer, if accurate description and identification of the photographs of a dead relation could count as proof. I merely mention this as a point to be remembered when considering the general argument with which I shall conclude this paper.

Both the women here mentioned, as well as the family of mediums mentioned in my paper of February 11th, when examined with black figures on a white ground, and *vice versa*, perceived the outlines of these figures, rings, bars, discs and segments of circles to have double outlines at definite parts, which behaved in a pretty definite way when the larger circular disc on which they were mounted was rotated. These gray double outlines for one direction of rotation would be carried round for a definite fraction of the circumference, when they would suddenly jump back to their original position, while, when rotation was made in the opposite direction, there would often be found a vertiginous confusion of vision to result. The subject was a puzzling one to investigate experimentally where one had only the word of an unstable subject to rely upon and where the results appeared to be so contradictory to ordinary experience. Strange and suggestive analogies to double refraction and complimentary color vision presented themselves, but the proximate solution appeared to me to be contained in the idea of irregular muscular strain on the one hand and color vision in correlation with the muscular sense on the other. In all the cases to which I refer the sensibility was quite stable on one side and perfectly normal, as checked by my own acute perceptions.

In one of my patients, a hypermetropic girl, I could give an opera glass into her hands at a time she had no perceptions of color on the affected side and by turning the screw so as to separate the lenses she saw all the colors in the order of their refrangibility. I was too cautious to let myself be deceived in any way; in all my complicated optical experiments I never found any attempt made to outwit me. In this case the reader will observe a strong analogy to those of the subjects of Binet and Fere and others, under the influence of hypnotism. In relation to the last experiment with the opera glass I may remark that its *naturalness*, strange as it may seem, is supported by the following fact. If you take a square marked into equal compartments, say a small chess board and fill in all the squares with patches of color so as to have an equal number of many colors in different patterns, it is quite easy to pick out any color, say a bright yellow or a red, and hold its pattern distinctly before the eye to the exclusion of all the rest which are just perceived as a confused mixture without any outlines. Another color may be picked up, when its pattern will jump out as before. The special effort of attention is here the analogue of the special optical arrangement which throws the image di-

rectly on the retina, when in spite of the inattention of the hysterical eye the visual centers are stimulated into conscious appreciation, the inference being that the action of the apparatus of accommodation is a normal factor in the psychical act of vision, though not a necessary one.

I had also studied cases of deranged vision in men who at the same time suffered from systemic disturbances that had an evident bearing upon the sensorial deficiency. Early at the year 1878, a soldier, Private D., whom I had under treatment in hospital on account of dysentery and liver derangement, informed me that he was troubled with visions of numbers of men who stood around his bed and appeared so real that he often got up to see if they were not actual living people. A short examination convinced me that he would present certain symptoms familiar to me as he showed the nervous temperament, intermittent heart, etc. This man's subsequent history of admissions to hospital justified the view I took of the hysterical nature of his nervous disturbances. He was frequently in hospital while stationed in Secunderabad in the Deccan, on account of dysenteric attacks of such a character as to confirm a suspicion I had that there exists a peculiar form of dysentery, or more properly hemorrhagic alvine flux, periodic in character which to a certain extent is analogous to menstruation.

When first I broached this idea to my senior officer in 1874, with reference to another soldier on the same station, the matter was regarded rather as a joke by him; but after the man had shown nearly a dozen admissions to hospital under the head of "dysentery," in little more than a year, a more serious attention to my view was demanded and the patient was sent to the hills, where he picked up wonderfully, increasing in weight and improving in appearance. Here too the intermittent heart was a very marked sign of the general tendency to neurotic disturbance; so marked indeed that the fainting fits to which he was subject were regarded as epileptic, before I took charge of the patient. In this case I could trace no abnormality of color vision in the slight examination which I made; but then, the weight of the disturbance of function being greatest in another direction, it is possible and likely that the volitional combinations, or perhaps I should say secondary automatic, were thereby saved. That a disturbance due to perverted directive activity, in which consciousness was primarily or secondarily engaged, was a factor in this case was evident from the fact that the very marked heart intermissions, sometimes occurring every three or four beats, were entirely absent during sleep; for I have felt the pulse beat calmly and regularly for three hundred strokes without an intermission during natural rest. I regarded the case as hystero-epileptoid, probably aggravated by bad habits. The inspecting medical officer looked on the man as insane.

To return to the case of Private D. A grand feature, identifying his peculiarity with those of the typical mediums whom I had examined, (I should also state that I have found periodic discharges of blood from the bowels to be present in a very well known and successful male medium whom I examined in London in 1872, and who also suffered from irregular action of the heart and insufficiency of ocular balance) was the onesidedness of his achromatopsia. For the other side the sensibility for the various colors was identical with my own as far as I could judge by comparisons with wools, glass and the plates in Benson's Principles of the Science of Color.

At first the confusion of color vision on the affected side was such that I could make no attempt to systematize the results obtained; for I found his statements as to the sensations produced by a given object vary from day to day. Remembering however that it was not a case of color blindness, in the accepted sense of the word, I was studying, but a something very different, a purely functional derangement in fact, as compared with an organic defect hereditary in character, I had to be content to take notes of what I found at the time, leaving the reduction to order of the results so obtained to a future investigation.

As my reference to disturbed color vision in this paper is general and illustrative of a theory or explanation of certain abnormal phenomena, I shall not do more here than say that D. showed analogous results to those already obtained, and that on the affected side he had a color system

fixed for the time but variable with the state of his health, all his functions tending to return to the normal state together. I hope to make the notes of his case, which extended over some months, the subject of a future paper.

About the same time I had under my care, in the same regiment, a young soldier, Private R., who suffered from periodic congestion of the liver, a vaso-motor derangement analogous to that from which D. suffered. This man also showed color vision peculiarities, some of them very similar to those of D. He was subject to palpitation and pain in the heart when excited.

I have recently sent on to the Committee of the Psychical Science Congress, of the Advisory Council of which I have the honor of being a member, a set of pulse tracings about six hundred in number, for the purpose of illustrating some of my views of the physiology of mediumism and which show considerable variation in the form of the pulse tracings of the two sides of the body. These were not specially selected for that special purpose but to illustrate rapports or attractions between different persons, which they do perfectly even to the establishment of the fact that during such rapports the so-called "spirit raps" may be heard, as was frequently the case during my studies in a government hospital under my own control. These raps according to all the analogies offered by the phenomena of the better known and established branches of science, correspond to the breaking down of strenes or tensions, originating from the nervous system of a living being and not otherwise, at any rate as far as the expenditure of energy is concerned, however and wherever the directive force or order for the expenditure of that energy may have originated. This is physics and physiology and not transcendental spiritualism; so that whatever may be our predilections or beliefs regarding another state of existence, we cannot shut our eyes and ignore the facts belonging to this order of existence or flout their legitimate explanation, even if we have to look at things in general from a little wider platform than that on which we have been accustomed to stand.

Now the reader will easily see that I have been leading up to a theory of extra-muscular activity which will account for a great deal of apparent contradiction and violation of the order of nature. This solution I long ago recognized as the true one; it was suggested to me partly by the observation that there was a relative deficit of urea noticed in the urine of a well-known medium after certain "physical manifestations," while he lay in a "trance," and partly on general principles of physics and of common sense.

Twelve years ago I published such a theory in London, giving it as my opinion that the mediumistic diathesis was "histero-gouty" in its character; that is to say, that the nervous element was a prominent feature in it and that, at the same time, there were certain imperfect processes of tissue metamorphosis which had their own psychical significance. We would not expect to see the high class psychical or even physical manifestations in the case of a typically healthy plow-boy, who only transforms his food into normal work, as evidenced by good sleep, good digestion and good, if somewhat dull conscience, with the chemical evidence of the same. But this theory did not suit the red hot spiritualists who were all for "Spirit power" and who accused me of narrowness, arrogance and bad logic. They did not see that energy is one thing and that its direction is quite another thing. Energy is the power of doing work; force is a derived space function of the quantity of energy and involves the idea of direction. These thoughts the earlier spiritualists confused, even the best educated of them, but now-a-days they are more amenable to reason, for they publicly recognize the fact that a very large per centage of that which even the most advanced of them claim to correspond to what was formerly called miracles, does not go beyond the organism of the medium or involve any other spirit than his own. But how their efforts are brought about is still the mystery and the theory is yet to be accepted by them.

Starting from the humblest form of living matter the highest efforts of the developmental process is arrived at by modifications of the same original stuff, and the psychical side of life cannot at any point of the great chain be shown to have suddenly appeared where some faint trace of it did not exist before. So

when muscle is special agent for the expression of animal energy we have in correlation with it the grown up and developed psyche which started merely in irritability or reaction to stimulation on the part of the original protoplasm. But what do we know of the nature of protoplasm or of worlds, outside of appearances and the chain of logic with which we connect them? Facts reign supreme and when new facts appear dogmatisms that set limits to their possibilities must give way.

It is necessary and sufficient for the explanation of the new facts to suppose that there is another mode of expression of the psyche, or animal soul, than through the agency of the muscular system. Surely it is not too much to ask for relatively as much as the original protoplasm had before the muscular system was thought of, it had a non-muscular mode of response to stimulation, which it felt too, within as well as without. It was the absence of development on the part of the psyche that made the growth through the ages so slow, but now that it has come to maturity, it is not confined to the muscular system alone. Let it kick over the traces and it will quickly learn to express itself in a new language and mode. If there is one lesson that the study of mediumism ought to have taught the physiologist it is that the organism has a spontaneous power of adaptation to even the most extreme conditions. The psychical science student knows that where single incoherent raps are at first heard, these steadily grow into a system of signals at the command of somebody's will; and where a few scrawls are at first made with difficulty, after a little tentative effort a learned treatise may quickly make its appearance from the pen of the unknown agent. And why? Because the psyche is quick to learn the use of a new instrument. Because it is ready and able to learn it, having already arrived at maturity! It was no wonder that the early spiritualists thought that in every instance a spirit *ab extra* took possession of the inanimate person of the medium and obliged him to act as impressed. It may be that such is probably the case in some rare instances, but that is not the question here. My business is to show my professional brethren that my experience with mediums and nervous sensitives justifies me in applying what I call the argument from perturbations to the establishment of the thesis that sensorial and motorial disturbance such as I describe, points to a loosening of the rigid physiological bonds which are found in the normal and typically vigorous organism. That loosening, I claim, is a stage on the way of switching aside the old organs and using the ether direct through its physiological or vital properties. What is there outlandish in such an assumption? I cannot see anything. It may be said that such an assumption involves the complementary hypothesis of an ethereal organism. Well what if it does? No one but the crudest and deadest materialist will any longer attempt to argue on the line that "the brain secretes thought or the liver secretes bile." It is too late to take up the argument of those who assert that the ego, the oneness of subjective life, is only a false appearance, powerless in operation and only the drift of the under current of the trillions of living elements that constitute the body, blood and bones of the organism. If we had no other argument to offer we might say that the ethereal body could have just as much a right to be composed of an innumerable army of molecules, as the earthly body with the ego for its King, its President or its Chief Executive, according to the temper and disposition of the little units themselves! But this is childish talk about a childish argument. It is the *oneness* of individual life that survives and that is equally represented in the earthly or any other body used by the psyche.

I have one concluding remark to make about muscle as an instrument for the expression of the spiritual activity of which each of us feels he is possessed, under whatever name we are pleased to call it. Muscle, like language, symbolic language, essentially artificial in its nature, is an instrument that preserves the individuality of its user. I believe there is a natural communal animal language that binds the individuals of the species among the lower animals together, and that it depends upon the use of extra muscular modes of force; muscle remaining the exclusive property of the individual for the preservation of its separate life. So in man, when the higher psyche resorts to the use of a lower mode of thought expression, with the loss of

muscular expression it may lose the sense of its identity, for the time at any rate, though not of its unitary activity and masquerade under any name that may be presented from within or without.

If a very much slighter effort would enable the vital unity to make use of the ethereal element of expression, (as would be the case if the supposition made above of the existence of an organic natural language of the species be correct, as no doubt it is), the slight or subliminal effort would be far below that required for the performance of any accustomed work through the muscular system, which as a heat engine is a notorious waster of energy. But as the integrity of the functional activity of the muscular system is, without doubt, necessary for the perfect maintenance of the personality, we have in the very fact of the dissipation of energy the index of a conservative process that cannot be too roughly or suddenly interfered with.

Does not such a view as to the part played by the muscular system throw a vivid light not only on the contradictions of mediumism, but also upon the difficulties hitherto offered by hysteria and idiocy and even some forms of insanity ?

I shall sum up my argument and appeal to common sense by giving some of the conclusions at which I had arrived before I brought this subject before the profession in the South, the medical men of Alabama, Georgia and Tennessee, who have always treated me with favor and consideration in my attempts to bring forward the results of my practical work and theoretical speculations.

The following paragraphs represent my views on the Dynamics of Mediumism.

1. That action at a distance, the prime problem of physics, may be regarded as an established reality in psychical science and in an analogous manner.

2. That, consequently, the muscular system must, in such an event, be supplemented by some other machinery for the transformation of energy.

3. That the muscular machinery of conscious thought is frequently dissociated from the actively functional organism, its inhibition permitting a free play to a finer mechanism, which it controls or overlays.

4. That such a conclusion directly leads to the adoption of the ether of the physicist, as the medium of communication between organisms which lie outside the normal physiological range of each other.

5. That the forms of intuition, space and time are replaced by the simpler quasi intuitional form *periodicity*, when an attempt is made to picture the subjective side of events in that mode of volitional activity less particularly specified than the muscular system.

6. That so for as the senses are concerned, the fact of periodicity is all-important, since without it the eye and ear cannot be understood as representing the unknown, under-lying reality of nature in any systematic way.

7. That, consequently, it is only the conscious relationship of the individual to the world that need be supposed to be interfered with when the individual is credited with powers which transcend our ordinary experience.

8. That the energy set free during the functional activity of the nervous system in its several parts, may be expended in producing disturbances directly on the ether, which disturbances of the ether, being so far only motions of matter, do not differ essentially from a muscular stress or a spoken word.

9. That the unanswered arguments of idealism, regarding matter as sums of sensations in fixed forms, applying equally to the ether as the postulated matter of scientific necessity, it is logically permissable to allow the subjective realitv (known in consciouness as the ego) in relation to the general store of energy and executive power, analogous to that maintained in consciousness under the forms of time and space and through the medium of muscle, matter and motion; provided the understanding can be statisfied that a more comprehensive form of quasi-intuition can be made available as a mode of systematized feeling.

10. That the true type of undisturbed motion being that of recurrence, it is more natural to attempt the construction of a working theory of the soul (tied down to matter as it is for its expression) by the contemplation of the ultimate small motions of matter rather than of those molar or massive motions of matter in the world around us into which the understanding and the judgment enter as much as the senses.

11. That as the fully manifested intelligence deals with generalities through the agency of thought and speech, so, on the other hand must the sub-conscious deal with *particulars*, except under special guidance, of which we can known little for certain, and so far can be legitimately represented in its final outcome as the operation of a sum of forces; for us at any rate it must return to consciousness for its interpretation as objective reality. Hence it can be seen how it is that mediumism may be the source of manifestations ranging from chaos (i. e. unsystemat ized particulars of feeling and motion) to the highest type of intellectual expression.

12. That the infinitely, or more properly indefinitely small or numerous, is not to be rejected as introducing an incomprehensible element into a theory which aims at unity, simplification and reconciliation, since we are constantly dealing with the same in all definite relations between our own bodies and external nature; being unaccustomed to such thoughts is no argument against their applicability. The mystery of mediumism is simply the mystery of matter in disguise and brought a little nearer to us through the introduction of the human organism as an instrument for its elucidation.

13. That the metaphysical thinker who accepts the fact of mediumism, even those which merely illustrate action at a distance, mechanical and mental, has no course open to him but to acknowledge the one substance theory in nature and to regard matter and form as the objective and subjective aspects of the spirit, which, however, can be only known in consciousness as the conditioned and relative.

14. That as no form can be regarded as final or absolute, so may matter present itself to the subject under aspects not immediately cognizable to the understanding, which has been developed along fixed lines common to the whole animal kingdom; the possibilities of human nature being demonstrated to overlap the penumbral borders of the unknown.

15. That the stability of the nervous system is the negation of mediumism; a thoroughly sound organism being for the time at all events, a complete barrier between the state known as this world and any other one.

# CLINICAL LECTURES.

## PREPATELLAR BURSITIS; TUMOR OF THE THYROID; TORTICOLLIS AND DEFORMITY OF NECK DUE TO VERTEBRAL DISEASE; OSTEO-SARCOMA OF FEMUR.

ROSWELL PARK, A.M., M. D.*

This patient is thirty-five years old, a cook by occupation. He confesses to specific infection a good many years ago. Two month ago he was in the hospital on account of a sprained ankle and at that time he was put upon potassium iodide and directed to continue the treatment after leaving the hospital. It is evident that he reads the newspapers for he has been taking somebody's celery compound which is advertised to cure a variety of ailments. Two or three weeks ago quite an outbreak of boils or carbuncles occurred and he is rather inclined to consider this a violent manifestation of the efficacy of the said compound. Ten days ago, without any injury which he can remember, his left knee became painful and swollen, and this condition has become aggravated.

In making the diagnosis we must consider the location and the character of the lesion. The tenderness and swelling were found limited to the front of the knee. The joint cavity was not distended, for the patella could not be pushed downward against the condyles of the femur

* Professor of Surgery, University of Buffalo General Hospital.

with a click, as is the case when it is floated away from its normal situation by a synovial effusion. Right in front of the patella there is a bursa, more or less distinctly developed in all persons, but especially large in those who are on their knees a good deal, as in women who scrub and men who polish floors and put down carpets. Clinically it is known that this bursa is a favorite site for a later manifestation of syphilis and such an involvement of other bursæ of the body is rare, only occurring from some unusual provocation. The typical syphilitic disease of the prepatellar bursa is a chronic inflammation with effusion, or the development of a gummatous tumor which may later break down into a chronic ulcer. Such developments, occuring without the history of traumatism and free from signs of active inflammation, may be ascribed to syphilis, and the diagnosis will be right in probably ninety-five per cent. of the cases. In this case we had something more to deal with. There were not only the location of the disease in the prepatellar bursa and the history of old syphilitic trouble without that of trauma to be considered; there were also present the signs of acute inflammation, redness, swelling, heat and tenderness. The diagnosis was, therefore chronic syphilitic bursitis with an implanted acute inflammation. The latter has been treated for two or three days by ice applications over cloths spread with mercurial ointment. In addition,the man has been taking potassium iodide.

As you now see the knee it is an example of inflamed syphilitic gumma breaking down to form a carbuncular mass. The acute inflammation has subsided. The use of the word carbuncular leads to the inquiry what is the difference between a boil and a carbuncle? A boil is a small subcutaneous abscess in which the tissue liquifies and escapes readily by one opening. A carbuncle contains what the laity term a "core," that is a mass of gangrenous tissue which breaks down slowly and usually leads to the formation of a number of sinuses. The essential difference between suppuration and gangrene is here illustrated, the former being molecular death of tissue, the latter death in visible masses. I can squeeze out a little pus and a free incision will hasten the breaking down of the gummatous mass. The further treatment will be poulticing to stimulate cellular activity and to hasten the process of separation of dying by the activity of the living cells.

---

This is a case of considerable pathological interest. The patient, who is now fifty years old, was grappled by the throat when twelve years old, in the attempt to throttle him. The neck was injured and we are told that black and blue marks corresponding to the fingers were left for some time and there remained always a little enlargement of the neck. This increased very slowly in size till last May, when it took on a pretty rapid growth and since then it has attained the present dimensions which you see. About six weeks ago it became very tender in one or two spots and he went to a local physician who detected pus and evacuated it by two incisions. During the last two weeks he has developed difficulty in breathing and, in the last four days, difficulty in swallowing solid food and even liquids. The man is cachetic in general appearance. The prominent angle of the thyroid cartilage is shifted a little to the left of the middle line. On this side the ala of the thyroid is normal and the left lobe of the thyroid is apparently not enlarged. The larynx itself is somewhat movable underneath the tumor, showing that there is no intimate attachment between them. On the right side, the sterno-cleido-mastoid and vessels are pushed away to the rear. The mass extends downward to the clavicle and upward almost to the jaw. It is firm and hard, it does not fluctuate at any point now although there is no doubt but that it has contained pus. It involves the right lobe of the thyroid *body* —I do not like to call it a gland. You have noticed that in answering some questions, he speaks with difficulty and with a peculiar hoarse tone of voice. I will try him with a glass of water in order that you may see that swallowing is difficult. These symptoms may be brought about on account of a warping of the trachea and larynx by pressure, or the vocal changes on account of paralysis of the recurrent laryngeal nerve by pressure, or possibly both factors may operate. On the right side of the neck I find a series of beady enlargements in the line of the chain of cervical lymph-nodes.

How can we explain the history of this

case and bring it into harmony with the present findings? Imagine that the enlargement, which is said to have existed for years after the original injury without change, was due either to the organization of an exudate thrown out during an inflammation of the sheath of the thyroid or to the formation of extravasation cysts from blood poured out into the thyroid body itself. Or we may suppose that there was, prior to the injury, a small cystic goitre which was increased in size at the time so as to become noticeable. The rapid enlargement since May, taken in connection with the apparent cachexia, suggests a malignant growth, whether carcinoma or sarcoma I should not pretend to say. The size has been, at least in part, due to suppuration but, even if we exclude malignant trouble, the abscess must have developed in a cyst with very thick walls so as to constitute practically a solid tumor. We have so little goitre in this country that such cases as this are rare.

In Switzerland, the Tyrol and other parts of central Europe, involvement of the thyroid is comparatively common. It has been a difficult matter to account for suppuration in the thyroid when there has apparently been no external lesion. No complete and satisfactory explanation as to when pyogenic germs gain access to the thyroid has been given. The most generally accepted theory is that under certain conditions of the system, these bacteria penetrate from the alimentary canal, passing through the natural barrier of mucous membrane and escaping the lymphatic filters, find a favorable soil for growth in the thyroid.

I will pass a needle into the mass and see if I can withdraw fluid from it. The advisability of operation will hinge on the result. The aspirator chamber fills with a quantity of bloody pus. The indication is plain,—to relieve pressure on the larynx and trachea by evacuating this fluid, whether we decide to remove the entire mass or not. However, the operation is not a matter of emergency, the patient is not just now in favorable condition and I can not anæsthetize him as he has recently eaten breakfast. I will, therefore, send him back to the ward and postpone operation till he has a few days of tonic and preparatory treatment.

About ten days ago I brought into this clinic a little child of nine, whose head and neck were twisted to one side. To-day the patient has returned for operation to relieve the torticollis. Very recently you saw a boy with a remarkable deformity of the neck due to disease of the vertebræ, not of the muscles. Since you saw him, he has lain most of the time in bed, with traction applied in the direction of the vertebral axis. You see how much brighter he looks and that the deformity is less than it was. I am now having a jury mast made for him, and in a few days he will be put into a plaster jacket and the jury mast substituted for traction in the horizontal direction. This will enable him to exercise and to enjoy himself in various ways.

The wry-neck of the little girl is an entirely different matter, consisting of a contraction of the sterno-cleido-mastoid muscle. Although some relief could be afforded by an apparatus to make a steady pull on the shortened muscle, the only rational treatment is tenotomy, on exactly the same principle as we would perform tenotomy of the tendo achillis or of any other muscle. Subcutaneous tenotomy was introduced by the erratic and rather peculiarly gifted surgeon Diefenbach, who showed not only what could be done by tenotomy but what perfect union could be expected in an hermetically sealed wound. Since his time, the use of tenotomy has been widely increased and, if we cannot reach a muscle by a small opening through the skin, we do not now hesitate to expose the muscle fully by a large wound, which is closed aseptically so as to make it as as nearly as possible like a subcutaneous wound.

So far as the causes of spasmodic and idiopathic torticollis are concerned, a great many theories have been advanced, and while only one theory can be correct in a given case, cases differ so widely that I am inclined to think that every explanation can be justified by certain cases. A very plausible explanation is injury to the sterno-cleido-mastoid during the process of parturition, especially when forceps have been used. Those of you who have seen forceps used, know the tremendous effort necessary at times in effecting delivery. The rocking motion which is so often practiced when the head, neck and body of the child are firmly wedged

in the maternal pelvis, and which has been condemned by many obstetricians, is quite capable of inflicting serious injury on the tender muscles of the infant. A certain amount of blood is poured out, which becomes organized into fibrous tissue which tends to contract as the child grows, just as scar tissue in superficial locations does. Thus the head is gradually drawn over and, while at first very little force would be necessary to oppose the pull, if nothing is done till the child is several months or several years old, a tenotomy is necessary. Usually these cases are not brought to the surgeon's attention until children are old enough to go about and become conspicuous by reason of their deformity. Then the mother's pride is touched and she seeks relief.

In some cases the trapezius is affected as well as the sterno-cleido-mastoid, and such cases are thought to be due to irritation of the spinal accessory nerve. There are also other theories of nerve irritation which it is more difficult to accept. In the present instance, not knowing the early history, I cannot tell you exactly what was the cause of the torticollis. I expect, however, to relieve the trouble by a simple tenotomy. At the upper extremity, where there is only one semi-tendinous end of the sterno-cleido-mastoid, it would be somewhat easy to divide the muscle were it not so closely surrounded by important vessels and nerves. Below, however, it has two heads, one attached to the sternum and inner end of the collar bone, the other well out on the clavicle. In this neighborhood are the external jugular vein, some other superficial veins and, a little deeper, the subclavian and lower end of the internal jugular vein, but they are deep enough and far enough away from the muscle to allow a tenotome of proper shape to be slipped in so as to cut the muscle from the rear forward. The skin is pulled down over the clavicle for the first incision, so that when the tendon is cut the wound will be closed by the natural retraction of the skin. The same precautions are taken in the way of cleanliness and asepsis as for any operation, for we want the wound to heal by first intention.

---

Eighteen months ago, this man was hurt by falling against a rail which struck the front and lower aspect of the left knee at the level of the head of the tibia. His knee became swollen and he was confined to bed three weeks. He then went to work. About eight months ago he began to notice thickening through the lower portion of the left thigh. Comparing the two limbs, you will see a very great difference. Observe, however, that he walked in with very little limp. He has consulted me, not because he is lame but because he has a great deal of pain in the knee, especially at night, when it is sharp and jerky like tooth ache. Some pain is referred to the calf, some to the inner condyle of the femur.

Might this be a tumor albus, a tubercular swelling of the knee? I can scarcely think so, for there is no muscular spasm which is so marked a feature of tubercular osteitis and there is no synovial fluid collected. The swelling, too, is in the femur rather than at the joint. I cannot imagine a man affected with tubercular osteitis with so much enlargement and not suffering more incapacity. There is no particular sign of syphilis except a few nodules in the neck, which might occur in almost anyone, and the darting pains at night which are not typical nor diagnostic. The man denies all syphilitic taint. Is this a tumor in the true sense of the term? Is it an osteoma or one of the other tumors which may grow in connection with bone? This mass does not grow from the outside of the bone, it is either a solid boney growth or something that has grown inside the bone and has expanded it.

I show you here a specimen of disease of the lower end of the femur, in which the end of the bone is simply a hollow shell spread out to the size of a child's head. Whether we have to deal with such a condition or with a solid growth, I can not tell to-day. The patient is now taking large doses of potassium iodide and if these relieve his pain, I shall be inclined to think that his trouble has a specific origin of which he is actually or feignedly ignorant. If not, I shall make an exploratory incision in order to make the diagnosis and determine the treatment. The diagnosis lies, in my opinion, between a genuine osteoma, possibly an osteo-chondroma, or more probably a giant-celled sarcoma which is also called myeloid from its common location in the

marrow of bone. I have seen many cases of syphilitic osteitis but never one producing so much enlargement. The swelling of the bone is abruptly limited and the shaft above is almost of its natural size. If this proves to be a myeloid sarcoma, which is essentially a malignant tumor, it will be disastrous to the limb and disastrous to life unless amputation is performed. Naturally the patient does not wish to sacrifice the leg unless it is absolutely necessary and I wish to give him the benefit of the doubt, and will, therefore, keep him upon anti-syphilitic treatment with the hope that it will relieve him, although I can scarcely express myself as sanguine in the matter.

(*Three weeks later.*)

Three weeks ago I showed you a patient with an enlargement of the lower end of the thigh which seemed to be of intra-osseous origin but which, it was thought, might possibly prove to be syphilitic. At first he improved under large doses of potassium iodide and had less nocturnal pain. We imagined that the enlargement subsided somewhat and the circumference of the thigh certainly became less, but probably on account of muscular atrophy from disuse. Of late, his pain has become a more serious matter and is no longer controlled by potassium iodide, while he is sure that the enlargement has increased. He has been seen by several members of the staff and has been made to feel that whatever is done will be for his best interests. The operation which I shall undertake will consist first of a simple exploratory incision and exposure of the interior of the bone. If I can convince myself that anything short of amputation will eradicate the disease, I will adopt it, if not I shall amputate the thigh. Tubercular disease making such a swelling would necessitate pain and muscular spasm and would almost certainly be accompanied by tubercular foci in the other parts of the body, and a dyscrasia due to absorption of ptomaines, i. e., hectic. Even if the trouble were—what I think it is—sarcoma, but originating in the periosteum, there would be so much pressure on the veins that the superficial circulation would be overtaxed and we should see deep blue lines over the knee.

The Esmarch bandage is applied over an antiseptic dressing so as to prevent hemorrhage for, if it becomes necessary to amputate, we do not want to delay. You will notice that the rubber ligature is put on as a broad ribbon, not a narrow cord, in order to prevent cutting into the tissues. The leg is scrubbed with potassium permanganate solution, followed by a bleaching solution of oxalic acid and sodium hyposulphite. A curved incision is made over the inner side of the thigh and the tissues, as I cut through them, appear healthy down to the bone. On the outer side, however, I do not like the feeling of the tissues, so that I will dissect off only the skin. I have now dissected nearly half way up the thigh before reaching a point at which the bone is of normal size. The bone is now sawed through and the next step is to find and ligate the open vessels. The sciatic nerve is pulled down and cut off. Many arteries can be seen and although they are not bleeding I like to catch them with hæmostats and tie them before slackening the Esmarch ligature. There is so much cut muscle surface that I shall do what I do not unusually practice in making amputations, and that is drench the surface of the muscles with a hot antiseptic solution in order to close the mouths of the small veins and capillaries. Otherwise there would be a good deal of oozing. You will see the rationale of this method of hæmostasis explained by the whitening of the surface which means a coagulation of albuminoids. It is quite possible to overdo this method by using too high a degree of heat. The stump is brought together by buried cat-gut suture of the muscle layer and the usual skin suture, and covered by the ordinary antiseptic pad. I am sorry that the man has lost his leg, but the enlarged bones and apparent involvement of the soft parts on one side indicated the extension of a sarcomatous process, whose further advance could be checked only by removing the diseased part and adjacent tissues which were at least under suspicion.

(Section of the excised bone revealed a central osteo sarcoma, while the microscope demonstrated in it relatively numerous giant-cells. The patient recovered under one dressing.)

---

Local Anæsthesia may be readily produced in about a minute by a spray of menthol, p. j; chloroform, p. xv; and will last from two to six minutes.

# COMMUNICATIONS.

## BI CORNATE UTERUS; PLACENTA PREVIA; CÆSAREAN SECTION.

WILLIAM VARIAN, M. D.,* Titusville, Pa.

The following case appears to me to be of sufficient importance to be placed on record.

On Wednesday, August 30th, I was requested by Dr. George W. Barr, of this city, to see Mrs. C., swede; aged 22; primapara.

Labor had commenced at the termination of the full period of pregnancy, on Friday, August 25th, and had been continuous from the commencement. Pains had been regular and persistent, and, at times, forcible, during the entire five days. A slight bloody discharge had persisted from the onset of labor.

I found the patient exhibiting marked signs of exhaustion, with a quick, weak pulse and anxious expression of face. Labor pains regular but feeble. Os uteri well opened and dilatable. No obliteration of the neck. Fingers entered their full length, apparently. Explored the entire cavity of a non-pregnant uterus. No presentation or sign of a fœtus could be discovered by intra-uterine exploration. Vagina and uterus apparently of normal temperature. The abdomen was slightly swollen on the left side, and extremely tender, rendering palpation difficult.

Palpation demonstrated that the fœtus lay almost transversely across the pelvis, breech downward and to the right, head in left hypogastrium, vertex and back presenting towards the abdominal wall externally. No placental bruit or heart sound could be detected, although the patient claimed that fœtal movements had persisted up to 9:30 of the same night.

A full dose of chloral and opium was at once administered with a strong stimulant in order to secure a few hours of rest and restoration, and tide the patient over until daylight.

Section made at 10 A.M. Patient had rested well although sleeping but little. Countenance less anxious and pulse not so weak and quick.

Present and assisting at the operation, Drs. Geo. W. Barr, Wm. Johnstone and Wm. Nason.

Operation aseptic in all its details. The primary incision through the linea alba disclosed the lower border of the omentum closely adherent to the abdominal wall and to the uterus, dark-colored, apparently devitalized, and approaching a gangrenous condition. The incision was carried through the omentum and uterine walls, which latter were exceedingly thin, not exceeding three lines in thickness at the thinnest point. At this thin point discoloration had commenced with some softening, and rupture was evidently threatened.

The amniotic fluid was small in amount, of a dark color, grumous, but free from odor. The fœtus, a female of apparently eight months development, was macerated, ecchymosed and discolored; the cuticle peeling off where handled. The placenta was prævia, being spread over the septum which divided the uterus into two parts. A careful examination with a finger on either side of the septum showed that it was thick, firm and uniform, apparently of the full thickness of the uterine walls. It extended from the left uterine wall just within the internal neck of the uterus to the fundus near and to the left of the right cornu. The septum was apparently uninfluenced by the expansion of the uterus during pregnancy, and was thicker and firmer than the walls of the impregnated cornu. At this examination no opening was found in the septum, nor any point where an opening had apparently existed, so that the impregnated cornu presented the appearance of a hermetically sealed chamber. But later a thin and yielding point was found, through which a soft rubber drainage tube was carried.

The adherent and devitalized omentum was stripped from the uterus and abdomen and removed. The uterus was closed by silk sutures. The abdomen thoroughly washed out and drained was closed with

* Late Lieut. Col. and Surgeon U. S. Vol.; Ex-Pres. Med. Society State of Pa., etc.

silk worm gut. The usual aseptic dressing was applied.

Patient died from exhaustion on Friday Dec. 1st at 10.30 P. M., having survived the operation a few hours over three days.

This case affords the following points of special interest.

1st. The unusually firm and thick septum between the cornua.

2d. The implantation of the placenta upon this septum completely occluding the entrance into the left cornu.

3d. The development of the uterus to the left and almost transversely, — a necessary result of this condition of things.

4th. The thick septum, covered with placenta and with a breech presenting against it. Making a vaginal diagnosis of the real condition impossible.

## A MEDICAL OBJECTION TO DANCING.

GEORGE L. BEARDSLEY, A. M., M. D., Birmingham, Conn.

Theseus, in "Midsummer Night's Dream," asks, "Is there no play to ease the anguish of a torturing hour?" His idea of mirth is akin to that of many who prate about "innocent amusements" to kill time or put an end to the megrims, either caring or thinking not for the *after-effects* of a revel. There is often a greater good done to a tired brain by a game than by medicine, but it is of vital concern to the person to be entertained that the sport has not too much rigour. Is dancing a jollity of this kind? This is the suggestion of the article now submitted. From a physical standpoint or on the issue of health it is susceptible of proof that the muscular fatigue and strain incident to this sort of fun is detrimental to the bodily vigor and endurance of woman.

Medical men, particularly specialists, meet often with patients who are nothing short of invalidism. They are walking valetudinarians who ought to be in a sanitarium and would be if they had the money. A large percentage of the feeble, nervous, chlorotic girls and women who frequent a doctor's office, are those who are obliged to eke out an existence with a body not put together to bear much of any burden, and yet because of a contracted purse must all day operate a treadle or measure calico or tend a carding machine or teach school. The public knows nearly nothing about the feeble energy of the majority of girls who work in our stores and factories for their bread and clothes, how small is their surplus of strength beyond what is necessary to the day's call on their nerves and muscles. The testimony of those who have particularly looked into the causes of woman's aches and invalidism, agrees with the saying of Pope that she is "fair by defect and delicately weak." Is it a marvel then that when such structures are taxed by the wearying gymnastics of a ball-room, their savings-bank of health early becomes insolvent? Graceful dancing is a no ordinary nor easy achievement; it requires more than a relish for light music or a lively company. There are few who are really artists in waltzing, and as in athletics muscle and agility are sine qua non, so to lead a cotillion or to step to schottische time involves a quick adaption of muscles that if weary or dull answer, too slowly for grace, the motions of a light-tripping partner. To dance with ease and becomingly every joint ought to be supple, every nerve fresh, every muscle limber, the entire body in a state of exaltation, not from excitement but physical buoyancy. And yet a great percentage of those who waltz or promenade at our public dances, engage in the pastime at the conclusion of a day's toil with not a moment of recuperation, and are not physically able to go through the steps.

A highly intelligent lady who is of delicate health and a close student, remarked to me recently that she danced because she needed the exercise. There was no gainsaying her need of recreation, but just how three hour's waltzing, and that is work emphatically, in a poorly-ventilated, crowded parlor could be a refreshing "exercise" is past my divining. It takes a robust, wiry, alert person to dance creditably, and my frail friend would be no more fit after

such an "exercise" to ply her calling the next day, than would a watcher be for a night's round in a sick room who had lost her sleep for a week. The girl who is compelled to labor all and every day for her board-money has gone through all the strain her machinery can stand and generally more. It is time when night comes to halt and give the engine a rest for the next day's action. A dance till midnight for the store-clerk, shop-girl, school teacher or dress-maker, is like forcing a trotter after he has barely won one heat to secure a second. The horse gets distanced and breaks down simply because he has been driven beyond his limit.

If dancing is too expensive a sport for those who earn their bread by the sweat of their brow and have no strength to spare, are the same objections tenable in the case of the wealthy society lady who has a retinue of servants, does no manual labor, has no responsibility to vex her and can sleep the entire day after a night of gaiety. If it only required massage, baths, nicely-prepared repasts and comfortable beds to insure a complete recovery from the enervating or depressing effects of hours of waltzing, those who belong to the Four Hundred ought to show no marks of dissipation. It does not follow, however, that because of so favorable surroundings those who lead the fashionable levees and are distinguished at every cotillion are not affected, their health not compromised, by excesses or irregular hours. The experience of physicians is that insomnia, neurasthenia, dyspepsia, hypochondriasis, nervous and organic infirmities generally, are very common among society women. It is a statistical truth that the "rest-cure" institutions and sanitaria thrive on material furnished from this class. These of le beau monde play out earlier than one would imagine; experience reactions in consequence of a life artificial and exciting in the extreme, that are highly exhausting, and keep up on the stimulus of the will until some piece of their machinery snaps under the high tension and they don the habiliments of a chronic cripple. Those of the peerage are by no means exempt from the ills the populace suffer, and if one, sitting in the lap of luxury, on whom even summer winds do not roughly blow, hasn't a constitution that can brook the wear and tear of ball-room feats, what is to be said of the over-worked and under-fed, the heirs of toil, who are bound to follow the folly of their high-born sisters? The question that concerns the mother and daughter is does it pay to indulge in a sport just to be in the fashion, or to drive the blues or dull care away, when nature protests against it? That it doesn't, is evidenced by the fair-sized list of ailing maidens, and mothers out of sorts, that are now a day acquaintances.

## MENTAL DISORDERS.*

JOHN CURWEN, M. D., Warren, Pa.

To the physician who engages in the study and treatment of mental disorders, the problem is presented of a condition caused by two forces acting reciprocally on each other. The bodily condition influences the mental, and the mental state acts on the body in different degrees and in varying force, at given periods; and the careful study of these actions and reactions is requisite to avoid mistakes, or errors, and to arrange in the most satisfactory manner the course of treatment to be carried out.

The tendency of the present period seems to be to give almost exclusive attention to the treatment of the varying bodily conditions, but it is a fact which the most cursory observation will confirm, that certain mental states will either add to or retard the progress of the mental disorder, depending on the intensity of action of the particular class of manifestations which may act on the individual, at any given period. These actions may be of a very direct and positive character, giving evidence of their influence in the plainest manner, or they may be indirect and insidious, requiring careful discrimination to discover their presence and mode of action.

* Read before the Penna. State Medical Society.

To attain a clearer understanding of the proper treatment of mental disorders, it is proposed in this discussion to consider first the bodily conditions which require special medical direction, and then the influence of the emotions, passions and affections, as they may exert a determining direction, for good or evil, in any given case.

Without attempting any special designation of the varying forms under which mental disorders may be ranged, it is sufficient for the object in view to divide the whole into two general conditions, the states of exaltation and those of depression.

It must be distinctly borne in mind that the modes of life, the social habits and customs of the community, the attention to hygienic rules, and a variety of subjects which may be classed under the general head of peculiarities of physical actions, which cannot be accurately defined, though readily recognized in individual types, have a more or less determining influence in the production of disordered bodily conditions, which lead on gradually to irregular action of the nervous system.

The principle which must govern in the treatment of all mental disorders is that laid down, so clearly and distinctly, by Prof. H. C. Wood, "that individuals must be treated and not cases." The intense individuality of the majority of people requires that their peculiar condition be taken into careful account in all efforts to formulate a course of treatment. The idiosyncracies in regard to certain classes of medicines, the peculiar and often unexpected effects produced in many persons by the administration of ordinary doses of medicine, and the irregular action of certain organs caused by disordered nervous conditions, require special care in the prescription of such medicines as would ordinarily seem to be indicated for the condition present. These deviations from the ordinary type can only be ascertained by careful experiment and observation, but they are frequently of such a character as to determine the issue in any given case, and excite alarm and distrust in the mind of the patient, alive to every unusual and unlooked for result.

In all cases of great excitement it is very important to consider carefully in what manner that excitement may be most readily controlled and subdued. If such excitement occurs in a stout, robust man, the primary indication is a free purgation, and the best medicines for that purpose are calomel and Dover's powder at night, followed by some active cathartic in the morning. The special effect of the calomel and Dover's powder seems to be in the peculiar action on the different internal organs and on the skin, giving a peculiar derivative action from the brain.

What sedative should be employed after the free action of these medicines must be decided by the peculiar susceptibility of the patient to the influence of sedatives. Opium, as a rule, will best be dispensed with, from its tendency to interfere with the secretions of various organs and its special action on the nervous system and the brain. The best sedative is a tonic, preferably the pyro-phosphate of iron (5 grain doses), with a small portion of compound tincture of gentain, regularly three times a day, with good food in such quantities as to support the system and provide a full supply for the waste caused by the unusual excitement. An occasional narcotic may be required, to moderate the excitement and cause sleep, and some of the most recent preparations as amylene hydrate, paraldehyde, etc., may be used for this purpose.

It has been, and still is the habit with many physicians, to use, chloral and bromide of soda, or bromide of potassium, freely, in full doses; but it has been found that this combination, continued for some time, produces often the very effect, in certain individuals, it was designed to relieve, a peculiar form of mild excitement with great confusion of mind, loss of appetite and great nervous depression, which can only be relieved and removed by the withdrawal of the medicines, entirely, and the substitution of some tonic and an ample supply of nourishing food, adapted to the special condition of the individual beginning with egg and milk and any other food which the stomach will bear. It must at first be used in small amounts, frequently repeated, and the intervals lengthened and the quantity increased as the strength of the patient improves.

In certain conditions of high excitement with violent demonstrations, the individual will be better if he can be placed in a room, with some one to watch him, and

kept free from all intercourse with others. When of a milder type, regular exercise in the open air, to a moderate extent, will be of great benefit.

There are, however, certain forms of excitement of high character, in feeble persons, where the mental powers are specially disordered, with great confusion and incoherence, where no sedative or narcotic has any favorable effect, and quiet and composure can only be secured by the use of pure rye whiskey, in half ounce or one ounce doses, three or four times a day.

In such cases the whiskey, to that amount, is a pure sedative with a tonic influence, and need only be continued until the excitement subsides and then be withdrawn, as the tonic and food given will be sufficient to keep up the strength.

An opinion prevails, generally, that it is not prudent to withdraw any sedative or narcotic which has been taken in large quantities by an individual, or where the person has been using liquor freely, for fear of unpleasant effects, but the withdrawal should be gradual. After many years' experience with all this class of patients, I am prepared to say that no bad effect will result if the narcotic or the liquor be withdrawn at once and a good tonic, with such food as the stomach can retain and assimilate, be substituted and used freely until the depression following the withdrawal passes away.

Cases have come under my care where great injury has been done by the administration, in mild cases of an asthenic type, of large quantities of whiskey to the extent of a pint, or even a quart, in twenty-four hours, and continued for several days. No system can properly dispose of such an amount without injury to some of the organs by which its elimination may be expected, and the consequent effect is on the brain, giving rise to an unhealthy action and a very uncomfortable feeling of lightness or stricture. In addition, the proper function of the stomach is interfered with, so that the appetite is diminished and the food taken is not properly assimilated.

It is more than doubtful if any case of nervous depression is ever benefited by large doses of whiskey, but rather by a course of careful feeding, moderate exercise and mild tonics.

With no disposition to deliver a lecture on temperance I may yet be permitted to say that very great care should be exercised in the administration of stimulants.

Where their effect is felt by the fullness of the head and a flushing of the face they are not of any service, but when they can be administered in moderate amount and no such effects but rather an increased action of the stomach and a feeling of relief from fatigue or lassitude are experienced, they are beneficial, and give tone and strength. This effect can generally be best secured by the administration of half an ounce, or in extreme cases of depression, of an ounce, three times a day, and continued for a number of days, but not after the system has rallied from the depressed state.

The individual is often impatient at the slow progress, but patient waiting is no loss, and to that patient waiting the individual must yield to be sure of gaining that which he really needs; a relief from a depressing and disheartening condition.

It is a fact impressed more and more by daily observation on the minds of the profession, that the large majority of cases of mental disorder at this time are of an asthenic character, and need tonic medicines and good diet from the commencement of the treatment.

A variety of proprietary preparations are in the market, recommended as tonics from the formula from which they are reported to be made up. The amount of tonic effect from either of the medicines in these preparations is so small as to be of little real benefit. What is needed is some of the preparations of the U. S. Pharmacopœia, which are well known in constitution and composition and can be used in such doses as to have full and beneficial effect as soon as the system comes fully under their influence. It is an injustice to the patient to have him use bottle after bottle of some proprietary medicine, looking for a good result, when a better and a speedier benefit can be obtained from the use of some of the medicines from the Pharmacopœia, the exact constitution of which is fully known, and the dose of which can be readily adapted to the requirements of the individual.

When cases of depressed mental disorder are met, the condition requires a different course from those of an excited character. The depression is caused, in the great majority of cases, by some disorder of the general system lowering the

nervous tone and action, and must be met by a course of treatment calculated to bring up the whole system to a higher level and a more healthy condition.

The great trouble in these cases is the inability to sleep to the extent required to repair the loss occasioned by the daily worry and restlessness, but a course of narcotic or sedative medicines, steadily continued, does more harm than good by inducing a condition very likely to interfere with the process of digestion and proper assimilation which it is imperative to retain in the most efficient action.

An occasional sedative to break up the unhealthy restlessness, graduated exercise below the point of actual fatigue, cheerful diversion and moderate occupation, good and nourishing food regularly taken will relieve these conditions better than any means that can be used.

Great care will be required in the selection and administration of the food in the earlier stages of the different forms of mental disorder. In the excited condition patients will not eat on account of the peculiar excitement and the delusions which control them, and unless special attention is given to their regular supply of food and their eating it, they will suffer when the period of depression comes on, and they may not be able to rally from the great depression.

In cases of melancholy a very great reluctance is often manifested to the regular eating of what may be necessary to support the strength through the more acute stages of all forms of mental disorder by as great a variety of nutritious food, and in such quantity as the stomach will bear, so as to avoid the troubles likely to arise at a later period. Milk, milk and egg, eggs, beef, chicken, mutton and lamb, with a variety of vegetables and good bread may be given as the system will bear, but filling the stomach with soup and such matters, which contain very little nourishment compared with the amount of liquid taken, does not give the patient the character and quantity of nourishment which he really needs.

Where great sluggishness of the circulation is found, regular massage and, where can be had, Turkish baths, will be of great service in assisting the action of the other means employed.

As a consequence of these morbid conditions, the mind will be strengthened and improved by the action of one class and injured and disordered by the indulgence in the other, and it is a familiar fact that many cases of mental disorder arise from the effect produced by the constant action of one or more of the emotions or passions leading to an exaggerated or perverted view of certain relations of the individual to others.

If these emotions, passions and affections are thus instrumental by their action in the production of mental disorders, it must be taken as a necessary deduction that they will exert a greater or lesser influence on the mind when it has become disordered. The clear inference is that every effort should be made to divert the mind from what may, by the plainest reasoning, have an unpleasant or injurious tendency to something of a different character, and thus, by the implantation of brighter and more healthy thoughts and feelings, drive out those which are doing steady injury to the mind. Every form of diversion and occupation should be employed to change the current of thought and feeling. This effort will be where the thoughts are all of an unpleasant, depressing character, and where faith and hope need to be steadily held before the mind of the individual, faith in the employment and steady application of the proper means to change the morbid to a healthy condition, and hope that the varied means thus used will in due time result in a return to a healthy action of the bodily functions and a natural condition of the mental powers.

The effect of trivial incidents in changing the current of thought and feeling should be made use of in the employment of every means that can be procured or devised to induce a brighter, healthier and more cheerful direction of each and every beneficent emotion and affection.

Acting, therefore, on the principle that an evil in any form can only be eradicated by the persistent effort to implant a good, the evil effects and influence of the maleficent passions and emotions, such as envy, jealousy, malice, hatred and all uncharitableness can only be replaced by the steady inculcation of faith, hope, love, joy, gentleness patience and temperance in words and works, no effort should be spared and no labor should be considered too great to be employed to bring about such beneficent results.

## SHOULDER PRESENTATION IN PRIMIPARA WITH CASE*

JAMES C. PEARSON, M. D., Mitchell, Indiana.

On the 13th of November last, I was called in great haste to see Miss E. When I arrived I found two physicians in attendance. On examination the head of the child resting in the left sacral iliac junction with the right arm and hand prolapsed at the vulva. Impaction strong; the mother badly prostrated and weak. She had been in labor about 20 hours, under care and guidance of a midwife. Her physicians had been unable to return the arm or turn the child, deliver and relieve the woman. The child was dead. The womb had long since been drained of its waters and contracted closely about the body of the child, which rendered it impracticable to return the arm, bring down the feet and deliver the child without great danger of uterine laceration or fatal contusion of the parts of the mother, and of failure to succeed in effecting the version. A fourth physician came to our assistance. The woman was so weak and prostrated that we decided that the only mode of procedure left us was to amputate the arm, eviscerate the chest and abdomen, then deliver. After the surgical operation of amputating the arm, eviscerating the chest and abdomen of the child, the two practitioners first in charge of the case returned to their homes to get other instruments. The woman's strength had failed to an alarming extent, and it began to look like she certainly would die without relief, for we had done everything to sustain her strength in the way of giving her spirits vini gallici. We then gave her fluid extract of ergot in teaspoonful doses every 30 minutes, and after taking the third dose her pains grew stronger, at which time another practitioner came to our assistance, and by the use of the blunt hook we delivered her of the remains of a male child. The mother, after protracted cardiac trouble, made a fair recovery.

# SOCIETY REPORTS.

## WESTERN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

*Annual Meeting, Kansas City, Missouri, December 27th, 1892.*

[OFFICIAL REPORT.]

The following is the discussion on Dr. Adams' paper, published in The Reporter, May 6, 1893:

### DISCUSSION OF ADAMS' PAPER.

Dr. Joseph Price: This is a huge subject for a discussion. The author has given us a brief and interesting paper and his conclusions conflict only slightly with mine. I think he covers too much territory in his treatment, but we will not quarrel over that feature of his paper.

In regard to the natural history and pathology I differ with him some. I believe that the pathology of these tumors has changed in the last twenty years. The numbers given in the total surprise me in the matter of color. In Philadelphia, I find more whites suffering from hard growths than blacks, and we have a huge colored population there. Mr. Tait calls attention to the non-existence of these growths in the black; that they are not known in Africa. During his student days patients with a hard growth were considered curiosities. Edinburgh physicians and surgeons tell me that they are on the increase. This corresponds with my own experience. I find that they are on the increase in the south and south-

* Read before the Mitchell District Medical Society, July 13, 1893, at West Baden Springs, Ind.

west. Dr. McMurtry told me that his country is simply full of large hard growths; that they are very common to what they were ten years ago. I have for a long time classified them as rapid growing myomas, the œdematous form of the myoma the most rapidly growing of all. The multi-nodular fibroids I am not willing to class as myo-fibromata; they are slow in growth, the myomas are rapid—some of them quite as rapid in growth as cystomata.

The author has called attention to two important symptoms in the growth of these tumors. The symptoms of pressure have been very marked, particularly in the history of the three cases given in full. In myoma, pure and simple, the pressure symptoms are not so marked. The tumor is symmetrical rather than œdematous, and sometimes disputive in diagnosis. This is also true in cystiform degenerations and large myomas. Myomas never undergo cystiform degeneration, at least in my experience. I will here allude to the average age of this group of sixteen—37 years, giving these patients a period of eight, nine or ten years for growth and for a continuance of these pressure symptoms and for retrograde changes so common and incident to the growth of hard tumors. In the first case we have some subsidance or diminution in size of the tumor. The Doctor doesn't give his reason for the removal of this tumor. In the second, the changes are scarcely perceptible. If my memory serves me right, the tumor remains a large, multinodular fibroid with marked pressure symptoms. In the third I have forgotten just what took place, but I will go back to what takes place in these tumors and I will use these drawings.

There has been a great deal said in the literature about these growths occurring in colored people. (You remember the old books in surgery say—femoral hernia in women and inguinal hernia in men. Some time ago I asked Mr. Gemrig how often this occurred in his experience, and he assured me that femoral hernia in women was quite rare. My experience in hernia doesn't agree with the old books on surgery. I have found inguinal hernia, single and double, quite common in women as well as in men. It is very curious how one book copies after another.) This drawing is simply a typical case of multinodular fibroid. All of these small tumors are fibromata, white and cut off almost like an onion—a huge number of small ones, some forty or fifty, studded this uterus. This tumor continued to grow almost imperceptibly for some nine or ten years, when the patient conceived and bore a child by a new method. I scarcely think that any form of therapeutic treatment—clay or mud or ergot or iodine or muriate of ammonia—would avail much in the treatment of cases of this character. You will find in this case that three tumors are pediculated—simply little pedicles well nourished. Just here I might allude to a huge group of cases treated in Philadelphia, by muriate of ammonia and ergot, pushed and crowded for years until the health of many patients was impaired, and many of them have submitted to section. You will remember Atlee and Drysdale persevered in the ergot treatment for many years, and wrote treatises on the subject, but they say nothing about it now.

This tumor (illustrating) is pure fibroid; a pediculated fibroid filling up the pelvic basin. The uterus was a perfectly clean one, not a semblance of another growth in the uterine wall. That was altogether exceptional. This was also a pregnancy terminated by the Porro-operation.

Now we come to an interesting variety (illustrating with drawings)—and they are not rare—of a fibroid early in its growth. Years ago it was classified as intrauterine, and many enucleations attempted and many women sacrificed. Here you have some of them expelled on the peritoneal side and one in the cavity of the uterus. The latter, well nourished, grows to a considerable size; the others scarcely grow to be perceptible. This woman was under observation for some time. At times there seemed to be diminution in size simply from a saline treatment together with some simple tonic. She lived at the wash tub. Finally the symptoms of pressure on the bladder become so marked that she decided to have it removed. I had no thought of this huge tumor. I looked upon this portion as being myomatous because it was rather soft. Below I could feel these smaller fibroid tumors but when I incised the uterine wall this thing protruded and was unquestionably undergoing sarcomatous change. I will return to this drawing in referring to the outcome of these

cases. They are for all the world like this (illustrating.) This was a huge tumor with ovarian and tubal disease, abcesses on both sides complicating each tumor. To my great surprise when I incised the uterine cavity I found inside something for all the world looking like roast beef and undergoing sarcomatous changes. Specimens were taken from both of these and pathologists assure me that they are sarcomatous.

This drawing is one of cystiform degeneration taking place late in the development of this tumor. Early in the history of the growth of the cyst there is very little inconvenience, imperceptible in locomotion, and vesical symptoms are not noticeable. But later, at the age of forty-seven or fifty, it grew rapidly and the pressure symptoms became very marked. This rapid increase in size was unquestionably due to the cystiform degeneration.

I have watched with care the treatment of these tumors for some years, and I have had opportunities to study and watch cases under about every known treatment. We have in Philadelphia, two or three enthusiastic electricians. Their cases are under observation and have been for some years. A large number of them have had hysterectomies performed. They are all well or dead. Some of them died while under treatment at the hands of the electricians. Deaths are about as numerous in the hands of the electrician as in the hands of the surgeon. Now we often hear some good old family physician, with a large and varied experience—and he has a right to talk—tell us in county or state or national society meetings, that in an experience of thirty years he has had say four cases of fibroids; he will mention some kind of treatment he tried for a couple of years and the patient got along fairly well, and concludes that operation isn't necessary. Now, sir, at the present time, we treat that gentleman very much as a shrewd lawyer would treat a witness on the witness stand. We handle that physician the same way as to appendicitis. We want to know something about the patient at the present time, where she lives, what she is doing and how she is getting along. It is all very nice to say that you saw that woman two years ago and have not seen her since and don't know anything about it. In the second case the Doctor tells us that she is now in bed and ill; he is very nice and truthful about the matter. The other physician tells him that it is apoplexy, but he tells us that it is a tumor that has downed her. A patient of mine was treated from time to time, by two excellent physicians in Maryland and reported as cured. Two years ago she removed from Maryland to New Jersey and got suddenly and acutely ill, when I saw her. They are all still reporting that case as a cure, and I am showing it over here in Kansas as a cure with water-colors. We expect every man to tell us all about his case, to give an account of her at the present time; to say nothing about one or two or three or four years ago, but to tell us where she is and how she is getting along.

For instance, to fortify my point, a man living at Chestnut Hill was treated for twenty-four attacks of appendicitis by twelve doctors. He was wealthy and could afford to travel between Jacksonville and Los Angelos. He was reported by a number of doctors as having been cured. In the twenty-fifth attack he was ill and dying and Dr. Agnew removed the appendix. He had a nice recovery, while Dr. Agnew has the specimen in a bottle. In the next case a man in Philadelphia had twelve attacks of appendicits and he had a fairly good recovery but never was able to go back to his business. I saw him in consultation in the thirteenth attack. His wife gave me the names of six or eight doctors that had treated him, and told me all about the treatment. Her husband was in collapse and I told the physician that he would be dead in an hour or so. They had him propped up on five pillows. I told the physician that operative interference would simply mean a dead man; that he would never come off the table alive. He asked me to tell the family, and I told the wife that her husband was very ill. She smiled at me and said "I have seen him as ill as that twelve times." I could not tell her that her husband was dying. I said good-bye to the doctor, asked him to have a *post* and he telegraphed me that the man was dead three hours after my visit, that the *post* would be the next afternoon at 5 o'clock. Now those six or eight doctors are continuing to report that case as cured.

In a recent case, six or eight months ago, my brother went to New Jersey to

operate for appendicitis, and the doctor and consultant and family wouldn't hear to any operative interference. They wouldn't have their boy touched with a knife, and he returned. A few days ago they telegraphed him to come again, and the doctor met him on the platform of the station and said, "Doctor, I am sorry; the boy is dead." Well, we know from prolonged study, observation and careful watching of these cases, something about the natural history of such murderous troubles. Now I am not criticising the paper, but it is just a little too broad and too generous. This is the only criticism I have to make. The author has operated and he has advocated operative interference, but I fear he has counseled a little too much delay, favoring renal symptoms and retrograde changes in the surrounding viscera—changes which are bound to follow delay in the removal of these tumors.

Concerning the early treatment of fibroids. There is a good deal of criticism these last few years, of Mr. Tait's operation for the removal of the appendages. I believe it was Hegar's treatment to establish premature menopause in favor of shrinkage and diminution in the size of tumors. I consider it one of the best operations in surgery. I scarcely know an operation that accomplishes so much. Surely trephining for epilepsy and brain troubles has not accomplished half so much. Hegar's operation is here to stay; it is a very valuable operation if done early in the growth of small fibroids. I am talking about fibroids, not myomata. It is worthless in myomatous growths and in rapidly growing œdematous fibroids, but in pure fibroids it is the treatment par-excellence if done early. The operation is simple; it is quick and it is safe. No patient should die from a removal of the appendages when done early for small fibroids; and if thoroughly done, if the tubes are removed to their very roots without leaving either tubal or ovarian stroma, the menstrual flow will cease and the tumor diminish in size. I have seen them diminish one-half from the metrostaxis that follows the section alone. I like to see it; it is curious that in small fibroids after the removal of the appendages, we have twice the flow that we do in pus sections or double ovariotomies or like troubles. I have said sufficient about this particular procedure; I value it.

Many accidents occur in the growth of large fibroids. For instance, an otherwise healthy woman carries a tumor for ten years; she marries and conceives. Large numbers of healthy women with uterine fibroids do conceive. And some few of them perish undelivered and without assistance. All are not near an educational centre or a good surgeon. It is simply surprising the number of women that perish with fibroids and deformed pelves. For instance, only a few miles from Philadelphia, right in the midst of surgeons and specialists, they, with a pelvis one inch in diameter, die in the poor-house. One day about three years ago, while out on the West Chester road, I spied a dwarf; she was six or seven months pregnant—a little dwarf with some form of kyphosis. I said to a friend who was with me, "There is a case for hysterectomy or "Porro," and I asked whose patient she was. They gave me the name of a physician. I did something I never would do again, I let the matter drop without trying to save her, because I thought they would hunt her up and see that she was cared for. But she went to a poor house within twelve or thirteen miles of Philadelphia and died undelivered. And so it is in many cases.

This woman (illustration) was dying, so I did this operation. The fœtus was away under the diaphragm; I couldn't have reached the internal os with a sound twelve inches long; nor could she have passed the product of conception had she aborted at the second or third month. So completely had the pelvis filled, it was difficult, requiring some amount of superpubic compression, to permit the passage of the catheter.

Now I do not mean to show any levity about these operations; they are difficult, trying and dangerous. Hysterectomy is one of the biggest hills in surgery to climb; I am not particularly fond of it. While you may think I am an enthusiast in abdominal surgery, I am not. I am getting ready to stop; I have had enough of it. But from a large experience and a long one, having dealt with a great variety of complications and in a great many patients, I feel it my duty to stand my ground and to preach hysterectomy—to preach removal of the appendages early—the removal of a healthy fibroid before it does mischief by pressure, before it cripples the

kidneys and before visceral lesions take place from pressure,—the removal of a healthy tumor from a healthy peritoneal cavity is one of the safest operations in surgery. The removal of a healthy tumor or one with a fixed pedicle, small—and it should always be made small—and the peritoneum hermetically sealed is one of the safest and surest operations in surgery. The patients should all get well. It is difficult to have perfection in all your work, I will admit. But if you can do it with perfection, all will get well, providing the kidneys are sound and no retrograde changes have taken place in the viscera.

In my first eight cases, all neglected—all in bed and dying, all ready to surrender life—the women said, "we have tried everything and now, doctor, I am willing to submit to an operation." Unpromising, some of them perfectly hopeless. Of the first eight I lost two, both malignant and both hopeless. In the first I had a sarcomatous sigmoid, unquestionably due to irritation and pressure; and in the second I had a sarcomatous cæcum extending up towards the kidney. Both absolutely hopeless; no possibility for a recovery and too late for bowel resection or anastomosis. I went in and I had to come out; I commenced and I had to finish. One of them lived four days and the other six.

A great many operations are simply attempted; men open the abdomen and get tired and stop; don't go on. That is simply cowardly. No man has a right to attempt the removal of one of these growths until he learns how, until some one teaches him how. It is of vital importance that he witness a few such operations, or serve an apprenticeship under some operator until he learns how to make a pedicle, and how to manage it. He had better keep his hands off if he hasn't learned how, or he will lose a large number of lives; but when he does learn how, he is ready for work.

Dr. Cordier: There were a few points left out in the discussion of uterine fibroids for all that Dr. Price, as well as Dr. Adams, covered the ground pretty thoroughly. I think the removal of the appendages, as we understand the pathology of uterine fibroids more thoroughly is going to be more limited in its application. This is due, I think, in the main to this: that as we understand the pathology better, we are learning the difference between fibroids and sarcomas. Many cases have been operated upon and the appendages removed for so-called fibroids, which have proved to be sarcomatous growths. The removal of the appendages for sarcoma does not stop these growths. There is another variety of growth occurring at the menopause; it may occur at any period in a woman's existence; it may occur in early girlhood. The President and myself assisted in an operation on a patient last spring, for the removal of a large fibroid of the œdematous variety. She was thirty-one years old. I have seen this variety in one patient as early as the nineteenth year. Removal of the appendages in a case of this kind would not do any good at all. Oedematous, it was so soft that if laid on the floor water would run out of it, much more so than out of a thoroughly saturated sponge.

These growths shrink; they appear at any age of a woman's existence; they are not attended usually with the hemorrhages that are common in the true fibroids. This brings up Mr. Tait's classification of fibroids. He says the terms "fibromata," "fibroid" and "fibroma" should be dropped from our pathological and surgical nomenclature, and the term myoma applied to all these tumors. Although this comes from Mr. Tait, it should not go unchallenged. There certainly is a difference between œdematous myoma or true myoma of the uterus, and fibroids proper. Mr. Tait says, that in his whole experience in fibroids, and it has been a large one, he has failed to find a fibroid tumor of the uterus in which the muscular element has not predominated. That is certainly contrary to all pathologists except Mr. Tait, and Mr. Tait is not looked upon as being a profound pathologist. There are better pathologists in the world than Mr. Tait. There may not be many better operators, especially in Europe; but we have one or two in this country as good and even better, I think. Tait is off in his pathology. Smith disagrees with him. The late Fourmet disagrees with him. There is another class of cases in which the removal of the appendages does no good, and that is the fibroid proper in which there has been cystic degeneration, the so-called fibro-cystic growth. These, while the operation may possibly check

the growth, do not shrink. It is the experience of great surgeons, especially gynecologists, that in pediculated fibroids —that is, a fibroid that has a long neck running out from the uterus—the removal of the appendages does not cure; it does not shrink them. It doesn't seem to me that the mere cutting off of the blood supply of these tumors is the cause of the checking of the growth. The ovarian artery supplies the smallest part of the blood to these growths, and the ligature never has gone low enough to include the uterine artery. I am not casting any reflection on Tait's operation where properly applied, but I wish to make this point: that as we understand uterine fibroids, the application of Tait's operation is going to be limited; it is being limited every day. Many cases of so-called recurring fibroid have proved to be sarcomatous growths.

One point in regard to the therapeutic treatment of these growths I have little faith in. Dr. Adams has thoroughly covered the ground and left very few loopholes for me to get at him in the discussion—that is in point of disagreement; but there is another side of this question. A patient will come to us with gangrene, the arteries protruding, etc., as the result of the prolonged use of ergot in these cases. Since I have been here, it has been my good fortune, or misfortune, to be called in consultation with one of the leading surgeons in the city. I arrived on Friday, and on Sunday he called me up by telephone and told me he had an emergency case, and asked if I would come out and assist him in the operation. I found a colored woman, who, I understand had been treated with ergot for fibroids. She had bled until she was pulseless; she couldn't raise her head from the pillow. The operation was quickly performed. An incision made in the abdominal walls discovered the belly full of blood and an extra-uterine pregnancy with a fibroid as large as a cocoanut, or may be larger; a tear of the broad ligament and fallopian tubes, extending so deep into the fibroid uterine structure that there was nothing left to tie—nothing remained except to do a hysterectomy, which was accordingly performed. This case I understand had been treated by ergot. I don't know who were her physicians; I don't know how long the treatment had been carried out. Possibly the surgeon is here and can tell us more about it.

Dr. LANPHEAR: The paper of Dr. Adams is certainly one that should interest us all for the reason that some cases of fibroid tumor of the uterus are inoperable. I think it may be laid down as a broad rule, sustained by the experience of every one who does much abdominal surgery, that every case of fibroid tumor of the uterus in which the growth is continuous, imperatively demands operation; but there are certain cases in which, because of peculiar circumstances, operation might be too dangerous to be undertaken unless in extremest urgency. The patient might, perchance, be too ill from other causes, as in two or three cases I have under observation at the present time. They might be too ill to undertake an operation; or on the other hand they may be in the class of cases that comes under the observation of Dr. Adams in his clinic—colored people who were entirely too poor to pay the expense of an operation and the hospital bill. In each of these instances, then, we must have recourse to something beside surgical interference, however much we may desire hysterectomy. In such cases, we may have recourse to the treatment advocated by Dr. Adams, watching very carefully for symptoms of ergot poisoning; or we may make use of electricity. I don't mean by the use of electricity the treatment by acupuncture, but simply the galvanic current applied with an intrauterine electrode and one applied outside. In one case that came under the joint treatment of Dr. —— of this city, and myself, a very large fibroid tumor, we made use of electricity simply because the patient couldn't under any circumstances, undergo the surgical operation which we both advised. In this instance, the tumor was much larger than one's head. By the use of sixty to eighty milliamperes for a period of four or five months,—without puncture bear in mind, the simple intra-uterine electrode with the positive electrode playing upon the belly—this tumor was reduced about to the size of my fist. This was between three and four years ago. About two months since I examined her, and the tumor is still about the size of my fist and gives her no trouble. Although this

was a case in which we desired to operate but could not, we accomplished very much by the use of electricity. Ergot had utterly failed in this case. She had taken ergot from a prominent physician of this city for three or four years before she fell into the hands of Dr. —— and myself. So that in cases where we cannot operate, we may have recourse to the treatment advocated by Dr. Adams, or to the electricity treatment. My great objection to the therapeutic treatment or to the electric treatment is this: That, however skillful you may be, there is no possibility by our present means of making an accurate diagnosis. The case that has been referred to by Dr. Cordier, was one that my friend Dr. Adams had seen and had advised the use of ergot, and I think also of the pussy willow in the formula which he gives. She had taken this ergot for two years, or nearly so, under her attending physician. The operation mentioned by Dr. Cordier having been made, the specimen was examined and found to be that variety of tumor which we know as the œdematous myoma. In spite of the ergot treatment and in spite of the rest treatment, it had continued to grow indefinitely and would have continued to grow, I have no doubt, in spite of the most energetic use of ergot. In such a case as that there was no means to determine in advance of the operation, that it was of the variety known as œdematous. It couldn't be distinguished from a fibroid by any means except by the rapid and continuous growth, and yet ergot might have been used to this day without any relief.

Dr. Adams: What time did you operate on this woman?

Dr. Lanphear: I think it was last May, but she had been taking ergot I know for eighteen months or two years, according to the attending physician. He was present at the time we made the operation for the ruptured tubal pregnancy. In the third case, also under ergot treatment, operated upon by myself about four or five months ago, the trouble instead of being simply fibroid as diagnosed, proved to be carcinoma. I have a specimen that shows very beautifully, in still another case, that had been under ergot treatment by a medical practitioner in this city who said that he could cure the case. I removed, by supra-vaginal hysterectomy, a large fibro-sarcoma; it was as pretty a case of sarcoma as one could well imagine. I simply mention these cases to prove the assertion I have made that we cannot, in advance of an operation, tell whether a case is one of fibroid tumor, one of œdematous myoma, or one of fibro-sarcoma (fibrous sarcoma); and I am sure there is no gentleman here but will sustain the assertion that every case of œdematous myoma, as well as sarcoma or fibrous sarcoma, should under all circumstances be removed if possible. Therefore it seems to me that the treatment advocated by Dr. Adams should be limited exclusively to those cases in which it is impossible to operate.

Dr. Schooler: I was afraid that Dr. Adams' paper would share the fate of so many papers that are read just at the close of a session, and that the salient features would be lost sight of; but I am glad to see that it is not forgotten this morning. The intra-peritoneal treatment of the pedicle in cystic tumors, was a great step in advance in dealing with tumors of that character. The extra-peritoneal treatment of the pedicle in fibroids was equally as great a step in advance in those cases; and at the present time and with our present knowledge, it is practically as near to the ideal operation as we have—as we have with any other class of difficulties. I would not discourage investigation, and it is not the tendency of the profession to discourage investigation in any line; but I feel that with our present knowledge there is a very narrow limit for the other methods of treatment of this class of cases. I do not believe that they should be limited entirely, as the last speaker has said, to the treatment of inoperable cases; the limit should probably be broader than that; and it might be instituted in cases that have not caused serious symptoms. Pressure symptoms are absent; the tumor is of slow growth; and the urgency for operative procedure is not great—always keeping in view the fact that the delay should not be continued too long; that treatment should not be kept up until complications become too great to afford a reasonable opportunity for the safe removal of the growth by operative procedure.

So far as is concerned the operation of removing the ovaries and cutting off the circulation with a view to destroying the

vitality, or starving the growth, the method only partially accomplishes the object. But the blood vessels in all these pathological conditions are not in their normal position and they are not normal in size. The anastomoses are more frequent and the vessels are larger and more numerous; and removing the ovaries, or the ovaries and the tubes, as a rule, only partially accomplishes the object. The uterine arteries are not disposed of, and frequently the enlarged new branches and the enlarged old branches are not interrupted; and it is at best, in many cases, a blind attempt to control a portion of the circulation. Perhaps it would not be advisable to entirely cut off the circulation. When the circulation is cut off the growth is deprived of its nutrition and it shares the same fate that any other portion of the body, normal or abnormal, would share for want of nutrition. Gangrene or sloughing or breaking down would possibly occur in a great many cases, and, being enclosed in the addominal cavity, would be attended with bad results. But if it were possible to cut off the entire circulation, there would be little added to the gravity of the operation in removing the tumor, which could be done quite as easily as depriving the growth of the entire circulation and its consequent nutrition. When the pedicle is brought out of the abdominal cavity, or a pedicle is made and treated as extra-peritoneal, we have it in the most favorable condition for surgical treatment. We have it in a position where it can be observed, where the circulation is cut off and the sloughing is outside and is not likely to be taken up and absorbed in the quantity or with the rapidity that it would be if it were allowed to remain in the cavity. Hence the intra-uterine treatment of these growths does not give the results, and does not offer the advantages and the promise that does the extra-peritoneal method.

It has always seemed to me that the treatment of these cases by electrolysis, is a good deal like the treatment of tubal pregnancy by electrolysis, in that one is never sure of the diagnosis. We have some men in our vicinity who can recall a long list of extra-uterine pregnancies successfully treated by electrolysis; but I have always suspected there was something at fault with the diagnosis—the results have been too promising entirely, and the cures have been too rapid and too numerous.

So far as the administration of remedies is concerned, it has always seemed to me that it bore about the same relation to these cases that medical treatment did to prostatitis in the old man, not prostatitis but true hypertrophy—it was a good deal like pouring water into a rat-hole. Still maybe there are some conditions in which it does good. There are some gentlemen who have an abiding faith in the use of drugs; they no doubt sometimes do good without clearly preconceived ideas of just how they are going to effect a good result. For that reason I would not discourage the views set forth in the paper, nor the views of any one who is attempting to make an advance or to produce something better or safer than operative procedure in these cases. It would be a very great benefit and a boon to humanity if something less dangerous and less formidable would give equally as good results, but I believe that cases should be restricted to two classes; those in which operative procedures are imperatively demanded and those in which operative procedures are not among the possibilities.

Dr. Cordier: I want to say a word about cutting off the blood supply. I mentioned that a little while ago. That is the smallest part or principle underlying Mr. Tait's operation. As Dr. Price said yesterday, you must remove every vestige of the ovary and cut the tube just as close to the uterus as possible. It seems due to the nerve supply, or to the association of the ovaries with the uterus, that the removal of the ovaries does the good in Tait's operation. It isn't the cutting off the blood supply. It certainly shows that the presence of the ovaries has something to do with the growth of these tumors, from the fact that the removal of them in suitable cases, stops the growth of the tumor.

Dr. Dewees: Among a number of cases, I have one which may more or less illustrate the position the writer has taken in his paper. About two years since, there came under my observation a case which had been treated by three or four able men. She had a nodular enlargement of the breast close to the nipple, but without a depressed nipple; very painful to the touch, or from pressure of the garments.

She was at the same time suffering from irregular, intermittent or periodic excessive hemorrhages from the uterus. The case had been diagnosed by two physicians to be carcinoma of the breast, or scirrhus—at least the word cancer was used, for the patient told me that the others had diagnosed it as cancer. She was absolutely averse to any operative procedures. To me the question arose as to whether the excessive hemorrhages were due to a cancerous growth in or about the uterus, or not. The patient was thirty-eight years of age, an important point in the case. Dr. E. A. Switzer, of Salina, Kansas, anæsthetized the patient for me and I endeavored to make a thorough examination. I make suprapubic pressure with the left hand, with the right hand fixed against my body. With all the pressure possible I gather up the tissue and force it in as far as I can. I succeeded finally by getting my hand into the vagina, and my finger into the cavity of the uterus, and by so doing was enabled to make out what, in my judgment, was a fibroid tumor. It was very hard to the touch and was almost entirely within the cavity of the uterus. It was undoubtedly a submucous fibroid. I announced to the husband, who was present, that it was a beautiful case to incise the capsule and bring out the tumor, but he opposed it on the ground that she would not consent to it if she were in her senses, so I had to desist. The next thing to do was to give some medical treatment whether we could give promise or not. I resorted to ergot internally, together with arsenic and syrup of hydriodic acid, and in six weeks time the irregularity of flow and the excessive hemorrhage had ceased. The tumor undoubtedly had diminished, and within the last year her menses have become regular. The nodular enlargement of the breast has entirely disappeared. The woman is unquestonably enjoying the very best of health. She is now forty years of age and mensturating regularly.

The point I wish to bring out in this case is this: That it appears in my experience, limited as it may be compared to some of the shining lights that are here to-day, that the nearer the tumor is located to the uterine cavity, the more good effects will we get from the ergot treatment, and the further away it is located from the uterine cavity the less good effects will we have from the ergot treatment. It resolves itself to a nicety in diagnosis.

Dr. Ward: Dr. Adams has thrown the gauntlet down and I could not be truly friendly to him if I didn't handle him as roughly as possible. He will think I have gone square back on him if I don't. Some want to recommend Dr. Adams' treatment because there is something new about that treatment. But I don't know what he gives; I don't know what that medicine is nor where I can find it, nor what he expects us to do. I want to know what is this medicine that he gives besides ergot. Ergot is quite familiar to all of us so far as the *ergot* treatment is concerned. I am reminded by the reading of his paper, of a little experience I had last summer, with a case that came to me for treatment. She had been nineteen years a sufferer. The case has been reported, so I will not report it again. The patient had in her possession letters from Dr. Gross, Dr. Blackford and other prominent physicians in the east and west, who had examined her and said to her that there could be nothing done in the way of surgical operation, but "we will give you ergot; we will give you turpentine; we will use ergot by injections into the tumor," and in those letters they have outlined the treatment. They used blisters, and Dr. Gross especially recommended the German—or perhaps the English leeches; imported leeches anyway—and they depleted the lady so greatly that he finally had to say to her in his letter, to use but one at a time; that was sufficient, a good strong healthy leech. That lady had, at that time, a tumor probably as large as this spittoon, because her abdomen was full and had been for many years. But the doctor insisted that nothing like a surgical operation should be attempted; it would be suicide on the part of the patient and homicide on the part of the doctor. I hesitated. Now it seems to me that when we talk about ergot in these fibroid conditions, we are striking nothing new at all, but we are going over the same old ground that has been gone over for hundreds of years, I don't know how far back, and tried in every shape, form and manner, and discarded as perfectly useless in almost every case. Admitting that it

will occasionally do some good, no doubt by helping to control the hemorrhage, and may reduce the size of the tumor, it does not cure the patient, but postpones the doing of an operation until it is too late, when it could have been done safely when first observed. You postpone the operation until it becomes serious; until the patient is broken down or in a condition in which she can not be operated on. The treatment is not new except the new medicine that Dr. Adams has got here, and will tell us all about in due time; and if that be true, it is hardly worth while putting on record that we recommend the use of ergot in those fibroid tumors. Of course they must be defined; we must know what we have; they must be diagnosed accurately, and we must know that the *only* treatment is by going into the abdomen before we resort to operative interference. If ergot is to be used as a last resort, we had better make an exploratory incision; it is just as safe as cutting the finger nails, safer probably.

I remember very well one of my first patients. I was as green as I am now and maybe a little greener. I took counsel of my text-books and the instructions I received in college, and what did I do? I put the lady on ergot and all those remedies, and that dear mother and wife died a death that now I am ashamed to remember. There was nothing done but the ergot treatment; nothing could be done at that time. Now we have arrived at a stage where we do know that operations for removal of the appendages help the majority of such cases and cure a large number entirely, and that the operation is safe. Look into the pelvis and if you find that the appendages are so adherent that the removing of them would be tearing them out bodily, root and branch, and if the tumor be so adherent that it would have to be pulled out in order to be rid of at all, then do a hysterectomy. If you can't do anything, close the abdomen. Let us not be so cowardly as to give a patient ergot when she has a large tumor in the abdomen, and say to her that "it is the only thing to do for a year or two, and if you get through that year or two, if you should happen to be alive, then we will try an operation." Let us not do that in this western country.

I wish to refer to a case that came under my observation about eight or nine months ago. She lives in the country, and has a history of four or five years of suffering, most of the time in bed. She has an impacted fibroid filling every crevice of the pelvis. You can't get into the rectum for the fibroid condition. She has suppression of urine. That woman is now sick in bed. She came to me for an operation and I examined her and charged her too much money; I was too high priced for her; she was not worth as much as I thought she was. Her husband was very wealthy but he wouldn't pay the bill. She came to Kansas City to one of my esteemed friends, and he said to her "No! an operation would be dangerous. You are alive now, and if I were you I would go home." She went home and probably will never get off her back. When I saw her she weighed 170 lbs. Now she is reduced to a skeleton. Why? because everybody is afraid to touch that case. I believe hysterectomy could have been done and her life saved. I wanted to speak of this to show you that we are too careless and too cowardly, and we allow our patients to go home and suffer and die.

Dr. Young: I have a case in a country town in Iowa, which I was called to see last spring. She had a round smooth fibroid between six and seven inches in diameter. There is no pressure trouble, but there is a little loss of general flesh; she goes about the house and does her work. Her husband is a farmer and doesn't have a very great deal of means. They are good people; the lady is a good woman. I was called to see her in connection with the doctor attending her, to determine what was the matter with her, whether it was pregnancy or not. He and I made up our minds that it was a fibroid —solid fibroid. It has been over a year since the tumor was first noticed, or the enlargement there. She heard that I was coming down here to this meeting, and she wanted me to ask Dr. Price what he would do. Now she is able to do her work in a manner and get about. She has had three children in her time, but they are all dead. She is about thirty-nine years old. She says I must ask Dr. Price what she should do. They haven't very much money, and I am not able to do a hysterectomy; I haven't the skill to do it. Now I rise simply to ask these gentlemen what to do. We have simply given her ergot,

half drams three times a day for six months, and the tumor has apparently not increased any in size in the last four months. I rise to ask Dr. Adams and these other gentlemen what I should do.

Dr. King: Before Dr. Adams closes I have a question I want to ask him. In his paper he didn't give us the result in but three cases. Now I wish to know what the result was in the other thirteen cases.

Dr. Black: I should like to make just a few remarks owing to the fact it was apparent to me last night, in the paper the doctor read, that he stated his case with a degree of fairness that does not seem to be allowed by those who oppose him in his statements. I don't think that he claims that he can radically cure these cases by the administration of ergot. I think that very often those who are the advocates of any certain measure are usually misinterpreted. I don't think that Dr. Price would do that. There certainly will be some conditions following an operation which will not permit us to claim that the cure is radical as that term is usually employed. Now I had occasion to observe, merely incidentally however, some three or four years ago the work of Apostoli in this direction. I went there more out of curiosity than to make an effort to learn anything new; and to my surprise the extravagant claims that had been made for the method were not claimed by him at all. The only claims that he made in these cases, were that possibly he might reduce the tumors, he could certainly control the hemorrhages and certainly control the pains—which I believe is true, because I interrogated these patients personally and wouldn't accept the statements of the doctor. But no such claims as are usually made in behalf of electrolysis were made by the advocate of the method himself, or by his assistants. Another point that is well to consider: we frequently see cases, or at least occasionally see cases, where the patient is hardly aware of her condition herself. I recall several large fibroids—as large as a man's head—of whose presence the patient was not aware until attacked by peritonitis. One was a pediculated fibroid; I was called in to see her when she had suffered from acute peritonitis and she wasn't aware of this tumor, lying practically loose in the abdominal and pelvic cavity, until peritonitis produced adhesions. I removed that after the peritonitis subsided, by an abdominal section, the only thing that could be done for it. It appears to me too, that as Dr. Price said last night, it is well for us to bring up the testimony to the very date of the taking of the evidence; that would apply with equal force to all operative procedures. Let us see now after a hysterectomy is done, or any operation for the removal of these growths, what is the condition of the patient afterwards. Is she absolutely cured? I don't wish to be understood as being opposed to these operations; I think it is a thing to be done in all cases unless there is something positively contra-indicating it. Isn't it true that the pedicles will sometimes be left in communication with the cervical canal and will leave permanent fistules; and isn't it true too, that it will occasionally produce certain effects by dragging upon the adjacent organs after the tumors are removed. I am speaking now of extra-peritoneal operations.

These are things that ought to be taken into consideration. I have at present a case under observation, who was not aware of the presence of one of these growths. She was unmarried and a nullipara, and after attaining the age of fifty-four, some four months ago commenced to menstruate, menstruation returning at regular periods, every month for the last four months. She began to complain of dragging pains in the pelvis, and upon examination I found the whole pelvic cavity blocked with this growth. There was complete reversion of the axis of the uterus so that the os pointed above the pubes. The growth was intra-ligamentous and the cervix was involved. Now here is a case where a woman, four years after the cessation of the menses, after the menopause had been established, who has been carrying a tumor perhaps for months and perhaps for years, without any symptoms at all. There are no pressure effects from this growth. She urinates as usual, probably a little constipated; and yet when she is on her feet a great deal, she complains of a dragging sensation. This growth extends into the ligaments; it is intra-ligamentous; certainly one in which very little could be hoped for in an operation to make a pedicle. This would have to undergo a process of

decortication for removal. I take it that in some of these cases, probably a great many, the disagreeable effects of extra-peritoneal pedicle treatment might be obviated by the entire removal of the uterus in addition, so as to make it absolutely radical, if it could be done. In the case I speak of, I don't think very much could be hoped for in making a pedicle. In fact the question arises with me in this case, might it not be as well to watch the patient and give the treatment that the doctor speaks of? In fact I have put her on that treatment; on the very combination that he speaks of. Might it not be just as well to wait? The growth is not very large; the woman is away past the menopause; and unless some symptom be produced, and we don't get the effect Dr. Adams speaks of, wouldn't it be just as well to wait and see? That tumor might undergo retrogressive changes because the menopause has already set in, because the pressure effects are not very decidedly manifest and because finally, it would involve more than ordinary vaginal hysterectomy. It certainly is an operation that would involve considerably more—requiring either drainage through the vagina or stitching the capsule or ligaments to the abdominal wall. The statement has been made here by one of the gentlemen preceding me, in a line that I am more specially interested in, that we can hope for probably as little in the treatment of these fibroids by medicine as we can hope for in the treatment of an hypertrophied prostate by medicines. I think that his latter statement is absolutely correct, that the effect of medicines so far as reducing this hypertrophied prostate is absolutely *nil.* But little as I have seen of the work of Apostoli, I am sure to a certain extent it can control the symptoms if it cannot control the disease. And in some of these very large fibromata, if they can be reduced to the extent Dr. Adams claims, wouldn't it be easier than when they are very large and complicated in their surroundings, after the reduction to remove them?

Dr. Price: There are some few points that stimulate me to take the floor again. First of conservatism. We are all interested in that. Dr. Ward calls our attention to a patient, and this gentleman from Iowa also calls our attention to a patient, suffering from tumor. She is anxious and we are all interested in her. We have all had too many painful experiences from delay due to conservatism and conservative counsel—and due to high fees. Some of the most distressing cases I have known in surgery, have been due to a fixed fee by an operator supposed to be the only one in the land, at home or abroad. For instance, I remember very well years ago, early in my experience, one or two large cystomas that had been seen by the Atlees, one of them the wife of a poor farmer on the Reading road from Philadelphia, in which one of Atlees fixed a fee of six hundred dollars. They knew no one but Atlee. It was more than they could afford to pay; they could not burden themselves with such a debt. She carried the tumor and lived a long life of misery—she had to go to bed and stay there; and when I entered the room, some four years after Atlee saw her last, I failed to see her face over the tumor. It was huge—barrel-like. She was a little skeleton, very much like a child dying from marasmus or hydrocephalus. It was absolutely hopeless; she had a thready pulse. I told her husband she was dying and could only live a few hours; and I told her physician that I might just as well cut her throat as to incise that abdomen and attempt removal. She died that night.

Now, sir, it is possible to take too high a ground in many matters, nor do I think it will pay. I will just cite one case, a recent experience in my own practice. For instance last spring, or a year ago probably, some one called my attention to a poor woman in Texas, the wife of a church janitor. You can imagine her poverty, the wife of a Texas church janitor. The good ladies of the church wrote to me asking if I could take care of this woman if they made up a purse for her travelling expenses. I promptly telegraphed them to send her on. They placed her in a berth, left her in charge of the porter and paid her way to Philadelphia. I had a patrol wagon meet her there. She had been in bed about six years; treated in four states by thirty-four doctors. Conservatism! I am talking about conservatism, delays and procrastination. No man has a right to follow surgery that hasn't courage thirty-three vertebræ strong—a full column. Her whole condition was distressing; she was greatly emaciated, and

the travel had not benefited her. I waited three weeks for her to rest, and then a section was done and I fixed up the uterus. Everything was torn up; she bore the operation badly, but re-acted fairly well and recovered nicely. She had been six years in bed, and for awhile before going to bed, she had used crutches and she brought them along. She finally got so she could take a walk through the square in front of the hospital. I told her she could go home and she did so. Not long after, some good woman with more wealth—not the wife of a janitor—heard of her, wrote to her, traveled a hundred and fifty miles to visit her and found her making pickles, getting ready for the winter. This woman at once telegraphed me and asked me what my charges would be, and the fee I mentioned to her was no small one, I assure you. I stated my fee and she telegraphed to hold a room for her and have a nurse to meet her. That woman paid me for the two operations and for the board of the two patients. Now, sir, I would advise you to cast your bread upon the waters, and don't hesitate; if you are going to operate on the rich you must take care of the poor, and if you take care of the poor the rich will take care of you.

Now Dr. Adams and others have referred to what takes place in the kidneys and urine from pressure symptoms and delay. Two or three cases have been cited, and I will simply call your attention to the character of the pressure symptoms, by alluding very briefly to two cases only a few days ago—two weeks ago last Saturday. A prominent Kentucky operator, a man of good judgement and skill, telegraphed me that he had sent a patient on the Limited; at the same time a Trenton physician sent me a colored woman with scant urine, with a rather distressing letter, stating, "Doctor, I fear I will give you a death." The woman for the first three days passed between two and five ounces of urine; the Kentucky patient passed more, say twenty or twenty-four ounces. Both of them were being purged, and I found traces of albumen in the urine of both. Saturday a week ago, I did the two hysterectomies; both huge tumors; both with pelvic fixation; pressure symptoms as marked as you could possibly have them. The Kentucky patient, in the operation, fared easily. It was necessary to make a pedicle in both cases. Just here I will allude to what the Doctor said in his able discussion of the subject intra-ligamentary troubles,—because it is too important to drop. In all these cases large tumors are simply play compared with some of the smaller ones. You needn't fear the large ones if you once learn how to make a pedicle, and you can make a pedicle in any large tumor and you need not fear the broad ligaments. After the first operation the Kentucky patient passed thirty-seven ounces; the second patient passed seven ounces, a difference of thirty ounces in the two patients. Both re-acted nicely and the urine increased in the second patient, and in the other it lessened; one increased an ounce, or two ounces a day. Neither of them had nausea; both had been freely purged; neither of them had very much to drink for a day or so; it was withheld because neither were drained, and I wanted to drain the lymphatics so that they might digest what little fluid accumulated. I have referred to these two cases because that is just what takes place in all delayed cases.

I take just this position with patients coming to me with any ovarian trouble—I mean serious troubles, vicious troubles, large tumors—if the husband hesitates, if the patient hesitates, I simply say to them, "My good woman, please have this attended to while your condition is good, favorable and promising; don't wait a year until you see you are going to die and then come to me and ask me to remove this—when it takes only a feather to depress the beam! But while your chances are good and about perfect, have it removed! Don't wait until a year from now; that is the eleventh hour work; you must anticipate what will come." Nothing pleases me more than the fact that in many cases I have simply driven patients to early operations by telling them flatly "If you come to me in one year or two years, dying, I won't touch you; you must go to some one else!"

Now in regard to Paris. It is a delightful city; I have thought sometimes of going there myself; it is a very nice, pretty place to go to and get big fees from Americans. Just two incidents. Apostoli is a delightful French gentleman; no one has a right to derogate him or his treatment of Americans. He is very

much better than some other European tutors who class all Americans as tramps and globe-trotters. A very lovely woman from Oakland, Calfornia, had some tumor, and I received a letter from a prominent physician there asking me what my charge would be to come to California and do a hysterectomy—two full well-written letters stating that this lady had been in Paris two years; she had received careful treatment at the hands of Apostoli without benefit; the tumor contimued to grow, the pressure symptoms were marked and she decided, after two years tinkering, to have this tumor removed. My fee was too high, and the local surgeon removed the tumor. He did it well and she got along nicely. A short time after, I was asked to see one of the wealthiest ladies in Germantown, the wife of a railroad king. She has spent two winters in Paris and enjoyed it, and in all probability she will go back to spend the third and fourth. Apostoli says she has a fibroid. I scarcely agree with him. It is my impression it is advanced tubal and ovarian disease with adhesions. I failed to find a fibroid but I did find angry tubal and ovarian disease. Had I urged section in this case I could have gotten consent, but it was an unpromising case. She enjoys living in Paris and I left it very much to herself to elect what she would do, it not being a fibroid and not dangerous at that time.

A speaker has alluded to the broad ligaments. Many cases have to be decorticated, and you can't do them without. You must learn to decorticate and deperitonize them. You may incise the peritoneum clear up to the cornual level, to the very root of the tube, and strip down the whole anterior and posterior faces to the level of the internal os. *Never* make a pedicle of tumor tissue ; *always* make it of healthy cervical tissue and fix it in the lower angle of the incision. You can remove it if you like by the flap method—drop method ; flap the pedicle and stitch it as you would the flaps in an amputation of the arm. Amputation is an unsafe and dangerous procedure. It has been practiced freely in Germany by Schroeder, Martin and others. These men cannot do it with a mortality below from thirty-five to twenty-four per cent., and if these men cannot do it with better results, it is folly for us to try it. The complete removal of the uterus is an easy and fairly safe operation, but the results have not been so good as by the extra-peritoneal method. It may be done and quickly done, and it is not necessary to have a lot of instruments, crutches and the like, to push up into the vagina to define the vaginal fornix. After delivering the tumor you can open the vaginal fornix as easily as you could incise the hymen, cut out the tumor, leaving enough tissue on the two sides to make your flaps safe—simply make a window in the posterior vaginal fornix, tie off four or six stumps around the bladder on the two sides. It is a safe procedure and it is not necessary to rely upon crutches, guides, guarded crotchets and the like, to define the vaginal fornix.

As to the deterioration of patients. The healthiest and prettiest women in Philadelphia are women who have undergone section. In a beauty show, I believe the women that have had diseased appendages or fibroid uteri removed, would take the prizes in good looks, color, vigor and usefulness. In my clinic it is interesting to present these cases and call the attention of visitors to the fact that this woman, notwithstanding she was emaciated, useless and lived a life of starvation—had been destitute of the bare necessities of life, with a cruel and barbarous husband—has been restored to health and usefulness. Among the poor it is exceedingly common for the husband to contract disease during the lying-in, if I may call it such, of the wife. Any number of husbands, in the large cities, will contract syphilis while the wife is in bed after a section, and in three or four months, the wives come to me with syphilis. To me it is one of the most distressing features of the matter. First he contaminates her with gonorrhœa and she has to suffer the risks of section, and then he gives her some disfiguring scaly eruption that she has to be treated for for several years.

The retrograde changes alluded to are very common, and this full discussion has served to fortify my position in regard to early interference while these tumors are healthy. One gentleman has reported some interesting cases of sarcomatous changes. It is very curious that in all these tumors, in some form or other, retrograde change takes place. The allusion to sarcomatous change and the difficulty of recognizing the precise nature of the

tumor, is correct. But early in the growth of such tumors, before these changes, it is not so difficult.

In conclusion I want to say that this is one of the most complete discussions I have had the pleasure of listening to for some years. It is a very much better discussion than takes place where every speaker gets up with a compliment and sits down with an apology.

Dr. Adams: The discussion which the paper has received is an evidence of the importance of the subject. I thank you for the fairness with which each of you has handled the subject. It seems to me, however, that with everyone there has been caution displayed in putting definitely on record a choice of any particular method or operation or means of cure—to the same degree possibly that the author has done in his dissertation.

There are some questions asked which perhaps I ought to answer. Dr. King asks what became of the thirteen cases, the result of which I did not give. I have six cases that furnished the histories illustrative of my observations. These six cases had been under observation so long and the treatment had been carried out for a sufficient length of time, as I supposed, to allow some data from them.

The balance were cases that I did not feel justified in including, simply because you could say to me, "You didn't see the patient long enough; you don't know that it is true." One of them, as I told you, was a cystic tumor which kept increasing, and I recognized how useless the treatment was and advised an operation but did not succeed in getting it. In fact, in a large proportion of the cases which came under my observation, I endeavored to obtain an operation but didn't succeed. You must recollect that we have in this town no place where I could provide for patients except I put them in the care of the city. My clinic, of course, must be managed according to attendant circumstances. When a woman comes to me for treatment I must do the best I can under the circumstances, and only the best. It would be useless for me to say I can do nothing for you without operation. That might be my desire and might be the ultimate result. It is brought out in the discussion that under treatment the patient, if benefitted, was in a better condition for operation. That was the condition in the case in which I did not tell why I operated.

Unfortunately the discussion has covered so wide a field, and possibly my paper covers too wide a field, that it is impossible to take up all points; for instance, the question of pathology and histology of uterine fibroids, their origin and causation; the question of the growth, life and decay of the uterus, which enter into this subject. Certain operations have been advocated to bring on premature menopause, or the cessation of menstruation, in order to cause a cessation of growth. Just so, theoretically, in my treatment salix niger which is a sexual sedative, a repressor of chronic mucous discharges, a diuretic and tonic, combines excellently with ergot to bring on, theoretically, a therapeutic cessation of sexual activity and, in consequence of this, a cessation of growth. I believe that theoretically that is correct and answers Dr. Ward's question. There is no question about this fact, that uterine fibroids do, according to a law of nature, undergo atrophy without the help of a physician.

You cannot, no matter what your individual beliefs may be, get up on this floor and tell me that the observations of men capable of observation, carried on through years and with the best opportunities, is absolutely false. You cannot tell me that; you must accept the concensus of opinion of men all over the world. Now, I believe that when you take that under consideration, you cannot tell me that any one method is the only method; and I believe that I have been truly conservative when I say the treatment should be elective, according to conditions and indications. Courage without discretion, although you may have as many vertebræ in your spinal column as a serpent, is no better than the conservatism which means ignorance, sitting down and doing nothing. Not endeavoring to progress is not conservatism, although when they talk about conservatism they illustrate it by cases which have undoubtedly fallen into the hands of a great many men of such character. I am not objecting to operation. I say true conservatism takes a broad view of the field, and is willing to accept every means and method, and to leave out simply that which experience has proven to be false. I have endeavored in my paper to carry out that

line. I have assumed that a great many things which might be said about the life, growth and ending of fibroid tumors are well known to you without mentioning the question of sarcomatous degeneration. I wish to say that the part which the menopause plays is a moot question. You may believe that taking out the ovaries and tubes clear down to the uterus, will stop this growth, if done early in a certain class of cases—that that is the thing to do. And yet that question is disputed.

Woman is a dual individual; she has a life within a life, and you can take out the inner life without damaging the outer. And this too enters into my theory of salix niger. If the menopause brings about a cessation of growth, then the excision of the tubes and ovaries is certainly a correct operation. I cannot touch upon all these questions, but I want to cite at least one case. The statement has been made which might put me in a false light, that I saw a case of fibroid uterus in which I had recommended the ergot treatment, and she came under my treatment, or at least that I had seen her before the operation. I know I have in mind the same case because I asked when the operation was performed with reference to the case, and learned that there was ruptured tubal pregnancy and death, as the gentlemen stated—the death occurring before the physician could open and do the proper surgical procedure. That case I never saw. That case was put upon my treatment at the request of a physician who, I supposed, knew how to examine and diagnose what he was going to treat. In that case, I gave the formula and said, "if you have so and so, try it" but also said, "if it is like this case which you see lying upon the table—and I had a specimen right there, cystic tumor—if it is like this, operation alone is the proper treatment." I am not responsible because he had not something at the ends of his fingers, or possibly in the head, that ought to have bidden him be cautious. I believe she was on treatment for six weeks. I think they operated in May, for I distinctly remember that the time when I was asked the question was about six weeks before operation. I speak of it because I do not want to go on record falsely.

## CORRESPONDENCE.

To Editor of Medical and Surgical Reporter: In Dr. Edson's article in the Medical and Surgical Reporter on "Fads of Medical Men," he refers particularly to the knowledge of the hereditary constitutions of his patients as an all important guide to the successful treatment of disease; and cites the old family physician in "Elsie Venner" as an example. He certainly is the old stereotyped doctor whose opinion is so earnestly sought by his families, not only for their physical, but their social and moral needs as well; who always arrives in the nick of time and, if worldly aid fails, ferries them across the river Styx. A magnificent character, unheard of in reality and doomed to oblivion with the good virtuous heroine, and brave handsome hero of the old novels.

To the laity, whose knowledge of medicine is a "dangerous thing" because of its minuteness, this idea of heredity and *strong constitution* and *different from other people* is quite common even amongst the most intelligent classes. The inevitable result of physicians expressing to their patients surprise at the non-effect of medicines that may have been administered; or perhaps the doctor wishes to flatter.

The writer claims that it is this individuality of cases that makes the practice of medicine so uncertain. This is partly true. There would not be the same dose of aconite, for example, administered to a weak anæmic woman as to a strong man; and yet two strong men suffering from the same disease, would receive the same dose if a similar result was aimed at. The former is the difference between an adult and a child, the latter is Dr. Edson's so-called individuality. Of course there are idiosyncrasies to be guarded against in the use of some drugs but they are rare enough.

Medical fads are not the results of physicians running after something new, but the demands of their newspaper reading patients, that make them often unworthy worshipers at the shrine of quacks and charlatans. I need only instance the Koch cure for tuberculosis that immature child of a theoretical brain, whose apparent brilliant future was so ruthlessly nipped in the bud by the hands of practical physicians who, at the importunity of their dying patients, yielded, I am sure in many cases, against their better judgment.

Dr. Edson also refers to another cause of medical fads, "To the blind maze of uncertainty in which the physician finds himself, and hails with delight anything that promises hopefully."

There are of course *mazes* enough only we sometimes close our eyes to what is apparent, and search for something hidden, something that no one has yet discovered.

"You may probe, you may cut,
Up your case if you will;
But the same old diseases,
Will worry you still."

Dr. J. William White in speaking of the superb Agnew, expresses surprise at the extreme simplicity of his prescriptions. The same was said of Sir Astley Cooper.

The future field of medicine will look to the prevention, not the curing of disease.

J. Newton Hunsberger, M. D.

Skippack, Pa.

## GEOLOGICAL TIME.

In treating of geological time, as indicated by the sedimentary rocks of North America, Professor C. D. Walcott, of Washington, D. C., before The American Association Advance Science, conceded, at the outset, that it is uncertain and is in conflict with the teachings of some other sciences. The physicist, for instance, requires us to bring terrestrial time within the extreme limit of twenty or thirty million years. The geologist replies that he cannot bring his facts within such narrow limits. Sir Charles Lyell, basing his estimate on modifications of certain species of marine life, assigned 240,000,000 years as the required length of geologic time. Darwin claimed 200,000,000 years; Crowell, about 72,000,000; Geikie, from 73,000,000 upward; Alexander Winchell, but 3,000,000; McGee, Upham, and other recent authorities claim from 100,000,000 up to 680,000,000 years. Notwithstanding this wide divergence, all agree in thinking the duration of the globe so great as to make man's occupancy of it seem but a span.

The attempt in Professor Walcott's paper was to throw light on the problem from ascertained facts as to the evolution of our continent, which was outlined in the Archean period and has not materially changed since. Its areas were more clearly outlined in Algonkian time, since which the changes have all been above the level of the deep seas. Sedimentation as the result of denudation has continued with little interruption. During the Upper Cambrian time the broad Mississippi area was worn down and the mass removed was carried into the ancient Cordilleran Sea. The process then was rapid, as compared with similar work in other periods. Chemical denudation is by the taking up of material in solution. Murray, in describing the results of the Challenger expedition, says that 113 tons per square mile per year may thus be accounted for. Besides the lime, etc., precipitated from solution, there have been mechanical processes going on, as also the agency of organism. Most of this has been in comparatively shallow water.

Without following the steps in detail, it may be said that the conclusion reached by Professor Walcott distributed geologic time as follows :

| | | |
|---|---|---|
| Cenozoic (including Pleistocene), about.. | 2,900,000 | years. |
| Mesozoic..... | 7,240,000 | " |
| Paleozoic..... | 17,500,000 | " |
| Algonkian..... | 17,500,000 | " |
| Total time of sedimentary rocks..... | 45,500,000 | " |

In commenting on this table it should be said that the data for Archean time are doubtful. Also there are no sufficient data from the duration of animal life to fix geologic time back of about 10,000 years. The fact may be mentioned that while we have 55,000,000 square miles of land, there are 127,200,000 square miles of water.

# The Medical and Surgical Reporter

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 = 18 = 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, SEPTEMBER 23, 1893.

## EDITORIAL.

### LAW WARRANTS AND THE DOCTORS.

The doctors should be exempt from legal process and from suffering the penalties of violated law no more than any other class of the community. They should stand equally amenable with all others, for any infringement of civil rights or infraction of the penal code.

We are safe in the statement, and we feel the fact to be a peculiarly fortunate one, that nowhere in the civilized world is the judiciary cleaner motived, more enlightened in the principles of law and equity, more strictly governed and guided by these principles nor more impartially just, than is the judiciary of our States. In this fact, physicians, considering their many exposures, find their greatest security from ignorant, malignant or low motived prosecutions.

Legal processes against physicians are sought through widely differing motives. Avarice, or gain with the least expenditure of money, time and labor, are probably the chief ones.

The civil or criminal warrant is very often sought by the adventurer or quack, as a means of cheap advertising, to reach a class of people they could not otherwise reach. They have panaceas which they are anxious to impose on the credulous and ignorant. Not one of the not small family of adventurers, practicing deceit and fraud, speculating with poisons, ever brought forward a remedy that stood the test of science or effected a cure. The profession is always ready to accept whatever contributes to the art of healing—it is not indifferent to improved remedies.

It is well known by physicians that very many cases get well without any medication—it is equally well known that there are many diseases for which no specific has yet been discovered. Of these we name but two: consumption and cancer. Yet, for these terrible maladies, the cure of which has defied the skill and best genius of the profession for centuries, there is constantly coming forward some

adventurer, or syndicate of adventurers, who, for revenue only, seduce credulous unfortunates into the belief that an infallible cure has been at last evolved or discovered.

For the protection of the public health, the law, in the exercise of its right and in the discharge of a service inestimable in its value, provides a not too rigid inspection of food. Penalties are enforced for the sale of impure milk, decayed vegetables, impure or tainted meats. Even the great American hog, of the *four-legged* variety, does not escape this inspection. Yet the health of the individual and of families is left to the tender mercies of the trickery and deceits, and to the shameless imposition of the "sure cure" venders. These hucksters of marvelous remedies are permitted to go on trifling with human life unimprisoned, unfined and unwhipped.

For the practice and prevalence of these evils, viciously evil alike to individuals and communities, a damage and a reproach to legitimate medicine, the medical profession is not free from blame. It is only through the enlightened opinion, the teaching and acting of the profession, that communities can be brought to a knowledge of the mischief worked by quack preparations and quack practitioners.

Individuals and communities often need protection against their own superstitions and follies. Combating and overcoming these is largely the duty of an educated, experienced and honorable medical brotherhood and of a courageous medical press.

We appreciate the difficulty of "knocking out" public or individual superstitions. There are in every community, those who have a blind confidence in some panacea—only the teaching of experience will convince them of the absurdity of their faith. These superstitions exist not alone among the poor and ignorant, but can be found in quantity among those whose opportunities and station in life, place in their favor the presumption of common sense.

The unscrupulous medical adventurers, the "sure cure" men, search the earth for testimonials of the efficiency of their potions. To the names of some of those giving testimonials, the very euphonious and sweet-scented title of Professor is stitched on.

Figuring frequently in civil or criminal prosecutions is one whose characteristics are familiar to the profession, the blackmailer. He can wear garments of any cut or color, and he can travel under almost any alias.

In Indiana, recently, a verdict was obtained against a physician for alleged malpractice in setting a fractured limb. This precedent was followed immediately by four suits for malpractice.

In referring to these cases the *American Lancet* points a good moral: "We emphasize the fact that the Doctors could stop this state of things, because it was never known as a historical fact, that any malpractice suit was won against a doctor when all his fellows stood by him. We never knew a malpractice suit brought against a physician, unless some other doctor supported the bringing of the suit and promised to support the plaintiff by his own testimony.

"It would seem as if self-interest would induce every doctor to stand by his unfortunate brother, because, if that brother is mulcted of damages in court, it is but a short time when he too will be made to act as a defendant in a similar suit. It would seem as if self-interest alone would prevent any physician from encouraging or supporting a suit against any other doctor, even though he were his bitterest enemy. Certainly good common sense would teach any doctor not to play with such a dangerous 'boomerang' as malpractice suits against a brother doctor."

"There are plenty of blood-suckers in

every community that regard it as 'smart' to get all the service they can out of a doctor and then blackmail him after refusing to pay for the service they have received. If the medical profession of that neighborhood do not stand together in self-protection against this class of pirates, they will individually have occasion to regret it in the near future.

"The great curse of the profession in the past and in the present is, that it does not by its individual members stand shoulder to shoulder and meet the assaults of those who would degrade the profession. Were it strong in this practical brotherhood, it need fear naught from outside attacks."

With such a condition of facts there would be very few suits for malpractice. The quack medicine man would not be so ready to institute criminal prosecution of doctors for condemning his wares as useless, mischievous or dangerous. The truth is the blackmailer is always a quack and he is the bolder, as a trickster and a cheat, when he has a kindred spirit in a diplomaed doctor as his prompter and counselor. This is well illustrated by the recent arrest of an honored Tennessee physician, one standing high in his profession and in the esteem and confidence of the community in which he pursues his calling. What he did, he did in the interest of his community—and in maintenance of the dignity and honor of his profession. For this service, his profession and the community in which he labors and has his home, owe him a debt.

That physician is not of the best type, who, from fear of possible consequences to himself, does not give the warning of any dangers he may discern, no matter from what sources such dangers may arise.

The quack's invasions should be guarded against with the strictest of vigilance. It is a worse pestilence than any against which our quarantine protects us. They are unscrupulous and fear nothing but the detection of their brands, and this even, they do not fear sufficiently. They are compact of greed, low cunning and art, and succeed with impunity in smuggling their spurious goods into the homes of the unsuspecting and ignorant.

Charlatans can sue out criminal warrants for esteemed, honest and honorable physicians with impunity and with no other motive to serve than that of malice, greed and advertisement.

One strange, lamentable fact associated with these malicious prosecutions is, that there are those who set up the claim to be diplomaed graduates of reputable schools, to be honorable physicians and gentlemen, who *instigate*, encourage and promote these prosecutions.

There are counter proceedings, both civil and criminal, by which these men can be reached, and they should be made to feel their force as soon as they touch within the jurisdiction of the proper court.

It would be very surprising if, in the Tennessee case, the profession of the South, with its known fidelity to professional amenities, its splendid traditions, do not defend, as one man, their worthy brother, against an attack that has had its birth in malignancy and a wanton cupidity. Every little personal dislike and jealousy should be forgotten in the effort to defend a fellow and vindicate the profession. Give these ghouls a victory and they will seek other victims. There will be none secure.

---

A Paris wet-nurse has had an unpleasant experience. The Assistant Publique sent her an infant to nurse, from which she contracted syphilis. It was shown that the woman and her husband, prior to the arrival of the infant, were free from disease, and the woman had therefore no difficulty in establishing her case and securing 7,000 francs as damages. —*American Lancet.*

# CURRENT LITERATURE REVIEWED.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES

for September.

Dr. Nicholas Senn contributes a paper on

**Laparo-hysterectomy: Its Indications and Technique,**

in which the indications and mode of performing the operation are fully discussed. The author presents for consideration the following conclusions:

1. Laparo-hysterectomy is justifiable when delivery through the normal passage is impossible without the mutilation of the living child.

2. It is absolutely indicated where the conjugata vera is less than two and a half inches, when obstruction is due to fixed pelvic tumors and advanced malignant disease of the cervix.

3. Mutilating operations on a living child for the purpose of effecting delivery are no longer legitimate obstetric procedures, as laparo-hysterectomy and symphysiotomy are life-saving operations for both mother and child.

4. Hysterectomy after laparo-hysterectomy is only justifiable if the uterus itself is the seat of a life-threatening removable disease.

5. Elastic constriction as a hæmostatic measure should not be resorted to in laparo-hysterectomy before the delivery of the child.

6. The uterine incision should be enlarged to the requisite extent by tearing for the purpose of diminishing hemorrhage.

7. The visceral wound should be closed by four rows of sutures applied in such a manner as to absolutely arrest the hemorrhage and completely separate the uterine from the peritoneal cavity.

8. Laparo-hysterectomy is also indicated in the operative treatment of single, large myo-fibroma of the uterus in young women when the tumor is located within or near the uterine cavity.

9. In such cases the uterine incision should be closed in the same manner as in operations on the pregnant uterus, and the bed of the tumor should be packed with iodoform gauze, which is brought through the cervix into the vagina, thus serving the double purpose as a hæmostatic tampon and capillary drain.

Dr. Gustavus Eliot discusses the

**Disorders of the Nervous System Associated with the Change of Life.**

The following are his conclusions:

1. At the time of life when the menopause occurs the various organs of a woman's body are likely to be in a state of depression as regards either their nutrition or functional activity, so that the normal equilibrium of healthy action may be easily disturbed, and abnormal action, the manifestation of disordered function, may be inaugurated and perpetuated.

2. The cessation of menstruation is an event of great physiological importance, and is perfectly competent to produce grave disturbances of the nervous system, if any predisposition to them already exists.

3. The more common disorders of the nervous system occurring under these circumstances are functional in character, and are associated with disturbances of functions in other organs, and especially of the digestive, circulatory, and hæmatopoietic systems.

4. In their treatment, attention should be paid to improving the general nutrition of all the tissues of the body, and restoring each organ to its normal activity.

5. If, after all the other organs have resumed the proper performance of their functions, symptoms referable to a disordered condition of the nervous system still persist, recourse must be had to remedies which act directly upon the nervous system, either by improving its nutrition or by modifying and regulating its action.

Dr. William Buckingham Canfield reviews the

**Clinical Aspects of Immunity.**

As the result of his observations and those of others, he makes the following inferences:

1. Second attacks are by no means so common as is generally supposed.

2. The more marked the signs and symptoms, and the more lasting the effects of the disease, the less often do we hear of second attacks. Measles and scarlet fever leave usually no marks, while smallpox leaves a scar; recurrence of the latter disease is less often claimed.

3. Those who insist on second attacks should assure themselves of the character of the first attack, and not take unreliable testimony.

4. When second attacks do occur, they generally come on long after the first attack, the individual is usually weakened in some way, and the attack is invited by the ingress of a larger number of organisms than would cause a first attack; while such conditions as fear, worry, fatigue, constipation, exposure, debauchery, etc., favor the second attack.

Dr. Herbert Snow, of London, contributes a paper on

**Some Points of Importance in the Nosology, Pathology, and Treatment of Cancers.**

The author calls attention to the fact that the word "Sarcoma" has acquired in medical parlance a significance almost as vague as the obsolete "soft cancer." As the word is now employed, it designates almost any cell-mass, of uncertain starting-point—in addition to tumors arising in connective tissue. He also thinks that the omission from the text books of those tumors designated as "round-celled sarcoma" would be a distinct gain to pathology as they are either examples of mixed sarcoma, or else fall more correctly into some other division of cancers. So too, he would relinquish the phrase "myeloid" sarcoma. "Giant corpuscles" or "myeloids," he states, are little fibrinous masses entangling

leucocytes and are an indication of marked vascularity merely. They are not restricted to malignant tumors. They are common to tuberculosis, to processes of absorption or repair of bone as well as to sarcomata.

A point mentioned by the author of importance in the treatment of malignant tumors is that while the adjacent lymphatic glands should be extirpated in the removal of a cancer, it is not required in sarcoma, since the elements composing the tumor are not of glandular origin in the latter and should adjacent glands be enlarged it is a sign of general metastasis. In the removal of a carcinoma the adjacent glands should be removed even if they are not palpably enlarged.

Dr. James Hendrie Lloyd discusses

**Hysterical Tremor and Hysterical Anorexia of a severe type,**

reporting a case.

From his own observation, he concludes that the disease most simulated by hysterical tremor is insular sclerosis, or sclerosis en plaques. The points of this resemblance are as follows: First, the character of the tremor. In insular sclerosis the tremor is excited, and much exaggerated by voluntary motion. The movement of such a patient attempting to carry a tumblerful of water to his lips is characteristic. This movement is really not so much a tremor as a jerky to-and-fro motion. During repose, however, the tremor is almost, if not quite, absent. Second: The speech is often drawling, monotonous, or embarrassed. Third: The mental faculties are seldom involved, but the patient is often emotional. Fourth: The age coincides with that in which hysterical tremor is common; especially in women—from twenty to forty years. The points of contrast, however, are equally marked and definitive. They are as follows: First: The tremor most common in hysteria, that known as the "type Rendu," is persistent and very evident during repose. Even when the patient sits up it is much exaggerated, and imparts a sense of general tremor to the hand of the observer when he presses it upon the patient's shoulder. While it is much exaggerated by voluntary movements, and often is marked by waves of exacerbation passing over the patient's frame, it does not lose its essentially rythmical tremulous character, and become as jerky and incoordinate as in insular sclerosis. It is also much increased usually by simply watching the patient—a most significant fact. Second: While the speech may be affected, especially in typical hysterical ways, as aphonia, the drawling, stammering speech of sclerosis is not truly imitated. Third: The mental faculties exhibit hysterical perversions and lacunæ which are not common, in his observation, in insular sclerosis. Fourth: There are no pupil-changes or nystagmus. Fifth: Hysterical stigmata can always be elicited, as a rule, by an expert examiner.

Dr. W. T. Councilman contributes an article on "Gonorrhœal Myocarditis" reporting a case.

The remaining papers in this issue are: "The Full Correction of Myopia," by Dr. Edward Jackson; "The Clinical History, Nature, and Treatment of 'Milk Sickness,'" by Dr. J. Howell Way; and "Hæmolymph Glands," by Dr. Heneage Gibbes.

---

## THE MEDICAL CHRONICLE

of Manchester, Eng., for September.

The principal article in this month's issue is a paper from the pen of Dr. M. Muret, entitled

**A Contribution to the Study of Tubal Pregnancy.**

The author reports several cases and reviews the opinions of various operators. He sums up the results of his investigations as follows:

(1) It will be found useful, in accordance with the course taken by the abortion, to distinguish between simple complete tubal abortion, where the entire ovum is expelled from the tube, and imperfect protracted tubal abortion, where portions of the ovum remain in the tube (tubal mole).

(2) Complete tubal abortion, accompanied by more or less severe non-recurrent symptoms, leads to the formation of hæmatocele, which may take any of the known courses.

3. Symptoms of acute internal hemorrhage are less marked in complete tubal abortion than in rupture of the pregnant tube; but appearances of severe shock occur which may be explained partly by the painful tubal labor pains in very excitable nervous systems, and partly by the influence of the blood upon the peritoneum. Sugar may occur incidentally in the urine in the acute attack.

4. In imperfect tubal abortion hemorrhage leads to destruction of the ovum, and to formation of a mole in the tube. When the ostium abdominale is open the blood effused into the tube passes by it into the abdominal cavity, where it leads to the formation of hæmatocele. So long as the degenerate ovum remains in the tube it leads as in protracted nterine abortion, to increasing recurrent hemorrhage, resulting in enlargement of the hematocele. The clinical aspect consists, firstly, in tubal labor pains and expulsion of a decidua, then in often-recurring attacks of labor-like pains with symptoms of internal hemorrhage, whilst locally, firstly a swelling of the tube, then the formation of a gradually increasing hæmatocele can be traced. During the attacks symptoms of acute anæmia may appear in a high degree, but the most characteristic feature is frequent recurrence of the attacks.

5. Occasionally with tubal moles a high degree of attenuation of the tubal wall is found at the point of insertion of the degenerated ovum, even when the ostium abdominale is wide open, aud without there being much distention of the tube. This attenuation of the tubal wall may be best explained by a purely local expansion of the wall caused by the effusion of blood lying originally only between the wall and the ovum. It is probable that an increase of ex-

pansion and attenuation of the wall thus produced may occasionally lead to rupture of the tube at this place, even when the ostium remains open.

6. In protracted tubal abortion, with open ostium abdominale, the removal of abortional residue or the tubal mole, with conservation of the Fallopian tube, is to be regarded as the goal of treatment; in the most cases, however, removal of the whole Fallopian tube will be a necessity. Therefore, when protracted tubal abortion is diagnosed laparotomy is the only operative treatment possible, as every operation by the vagina is to be rejected.

7. Upon certain occasions and under conditions which are not thoroughly explicable, hæmatocele extra-uterina may be so constituted that it can be enucleated like a tumor. In laparotomy an attempt at enucleation should always be made before opening a hæmatocele.

8. The first period after interrupted tubal gestation occurs in the course of the first six to seven weeks following the complete termination of abortion or removal of the tube (in protracted tubal abortion). Subsequent diagnostic conclusions can occasionally be drawn from this condition of the catamenia.

In the "Clinic" department of the journal there is the report of "Some Gynecological Cases at Ancoats Hospital" and the report of "A Case of Scarlet Fever, with Infective Endocarditis" by Dr. Arnold W. W. Lea. The case proved fatal on the thirteenth day.

# PERISCOPE.

## OBSTETRICS.

### Sugar in the Urine of Pregnant, Lying-in and Nursing Women.

L. J. Berberoff, basing himself upon investigations,—unfortunately not sufficiently numerous,—concludes that lactine only appears in the urine when more milk than is necessary is secreted by the gland. It therefore appears in the urine from the third to the fifth day, when the function of the gland and its production increase, while the infant still requires but little milk. On the other hand, however greatly the mammæ may be developed, when the child sucks out the milk entirely,—*i. e.*, when the equilibrium or production and consumption is kept up,—no sugar is to be found in the urine. When, on the contary there exist conditions in connection with moderately-developed mammæ tending to arrest the production of milk in them sugar appears in the urine. Among these conditions must be included changes in the mammary gland through which sucking is arrested, cracked nipples, mastitis, etc. In fact, sugar was most frequently found by him in parturient women suffering from these disorders.—*Vratch*, No. 16, 1893.

### Method of Bringing Down the Arms After Version.

Magnus recommends a new method for bringing down the arms after version and delivery of the trunk, which should not be brought down too far before delivery of the arms. When these are about the neck, the hand should be introduced in the ordinary manner, two or three fingers being placed on the superior edge of the scapula, which is gently pressed downward. This will cause the arms to move suddenly and to come down without any further help. Others besides the author have successfully made use of this method.—*Ugeskrift for Lager*, 1893, p. 62.

### A Case of Inversion and Falling of the Puerperal Uterus.

Primipara, aged 27. Fifteen minutes after parturition, the uterus became inverted simultaneously with the expulsion of the placenta. About an hour and a quarter later, Drefer was able to make the reduction. Recovery followed. Contrary to the opinion generally accepted, that the fundus uteri is the starting-point in inversion, the author emphasizes the fact that one must consider that inversion is effected from below upward, which assertion is fully confirmed by the case in question.—*Norskmagazin for lagevidenskaben*, L, iii, 10, Christiania, 1892.

## NEWS AND MISCELLANY.

### Prescuted on an account of a Postal Card.

Dr. James E. Reeves formerly of Wheeling, now of Chattanooga has been sued for damages on account of the following postal card, written to Dr. Mettner of Cincinnati:

CHATTANOOGA, AUG. 14, 1893.

*My Dear Doctor:*

I have seen your name in Amick's pamphlet. Please give me the outcome of your experience with the so-called "chemical treatment" for consumption. The enterprising managers have within the last month made Chattanooga a sort of head-center for sending out in the secular press wonderful cures which are pure fabrications. Not a particle of proof can be furnished that a case of tubercular consumption has been cured, or benefited by the so-called treatment. Has Cincinnati sold out and moved to Chattanooga? Verily, it seemes so. Speak your mind fully to me.

Sincerly yours, JAMES E. REEVES.

Dr. Reeves is full of fight, and says he will expose the whole thing in court next October with great pleasure.

## Galenical Preparations

MANUFACTURED BY

## WILLIAM R. WARNER & CO.

MANUFACTURERS OF SOLUBLE COATED PILLS.

FOUNDED 1856

### Standard and Officinal Preparations for Physicians Only.

#### PIL. PHOSPHORUS, DAMIANA ET NUC VOM.

(Warner & Co.)

℞ Ext. Damianæ, 2 grs. | Phosphorus, 1-100 gr.
Ext Nuc. Vom. ⅜ gr.

Med. prop.—Aphrodisiac. Dose, 1 to 2 pilis.

Of this combination it has been said: "It re-illumes the fading spark and revives the vital forces."

PER 100, 90 CTS.

#### PIL. ALOIN, BELLADONNA AND STRYCHNINE.

(Warner & Co.)

℞ Aloin.....1-5 gr. | Medical properties—
Strychnine.....1 60 gr. | Tonic, Laxative.
Ext. Belladonna..⅛ gr. | Dose, 1 to 2 pills.

Try this Pill in Habitual Constipation.

PER 100, 90 CTS.

#### Pil. Sumbul Comp.

(Warner & Co.)

DR. GOODELL.

℞ Ext. Sumbul . . 1 gr. | Ferri Sulph. Ext, . . 1 gr.
Asafœtida . . . 2 gr. | Ac. Arsenious . . 1-40 gr.

"I use this pill for nervous and hysterical women who need building up." This pill is used with advantage in neurasthenic conditions in conjunction with Warner & Co.'s Bromo-Sodc, one or two pills taken three times a day. PER 100, $1.00.

#### Pil. Lady Webster.

(Warner & Co.)

℞ Pulv. Aloes . . 2 gr. | Pulv. Rose leaves . ½ gr.
" Mastich . ½ gr. | M. Ft. one pill.

This is an excellent combination officinally designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when taken in doses of one pill after dinner. PER 100, 25 CTS.

BY ALL DRUGGISTS OR BY MAIL.

HEALTH! REST!

# TO PHYSICIANS

Desiring to send patients away from home for change of scene, in connection with systematic regimen and oversight.

## THE JACKSON SANATORIUM

offers exceptional advantages and attractions.

This institution is under the personal care of a permanent staff of regularly educated and experienced physicians.

Location, 1,200 feet above sea level, in a woodland park, overlooking charming upland and valley views of Genesee region. Pure spring water from rocky heights. Clear, dry atmosphere, free from fogs and malaria. Perfect drainage and sewerage systems. Delightful walks and drives.

Elegant (brick and iron) fire-proof main building and twelve cottages, steam heated, and designed to meet every requirement of invalids, or seekers of rest and quiet.

Extensive apartments for treatment arranged for individual privacy. Skilled attendants. All forms of baths, Electricity, Massage, Swedish Movements, etc., scientifically administered.

**Culinary Department under Supervision of Mrs. Emma P. Ewing,** Superintendent of the Chautauqua Cooking School, whose reputation as a teacher of scientific and hygienic cooking is national.

Comfort without care; freedom from taxations of fashionable life and from the excitements and temptations of popular resorts. Especial provision for quiet and rest, also for recreation, amusement, and regular out-door life. Telegraph, telephone, electric bells, safety elevator, open fires, and all modern appliances for comfort and health. On direct line of Del. Lack. & West. R. R. between New York City and Buffalo. Only 9 hours from New York.

**Established in 1858.**
**Open all the year.**

## ORIGINAL ARTICLES.

### SURGERY OF TUBAL PREGNANCY.

JOSEPH PRICE, A. M., M. D., Philadelphia.

As we look back across the years we note that progress in some of the more important lines of medicine and surgery has not been rapid, that many of the simplest surgical procedures, those of inestimable value to the profession and to suffering patients, have been of comparatively recent devisement and practice. The steps are slow that grafts most that is best into our every science and art. We put to the severest tests of science and experience every product or result of the highest genius. We are not satisfied until we have tested and know values. But for all this our advances are not the less certain and reliable. Every innovation must confront prejudices, opposing arguments, stand the tests of many experiences, before it can be regarded as having come to stay. We prefer our roads should be made for us and be well traveled before we take to them. We throw ourselves upon the resources of our science and art as we find them and find that to master them is the best equipment for our work. We are averse to wasting time in the discovery or invention of new methods. We are rather impatient with the "my method" gentlemen of the profession. In making choice of a watch we prefer the Geneva to the Waterbury. In surgery our choice of methods is equally easy, the guiding is that of a principle equally rational—it is to prefer the simple, direct, accurate and successful in result, the method employing a minimum of manipulation.

We are not so eager for the invention of something new as we are for the wisdom to use what we have at hand, to so improve and adapt our methods to our varied needs as to carry order where confusion now exists. Do not understand, that we object to the new, to innovations; we would not fix a limit to our resources. We want investigation, research and invention to have free wing, but we can only gain more and better by using wisely and energetically what we have. We want enough interest in the "ways and means" at our command to take all professional drowsiness out of us. It is as a means to something better that we believe in the old. The old is good only as it can be used to evolve something better. We have no sympathy with modern conservatism as exhibited in medicine and surgery. It is the spirit of delay, of postponement, and regards all changes as deterioration. It conserves the old because it is old—because that is the way the old Beacon street or Knickerbocker dad did it. It never has a new day—spends all its time living over yesterdays. We are not feeding on old reputations, resting by old landmarks, we would mark some growths of our own. I desire for the profession of the period some triumphs. From an operative standpoint I consider the success of surgical interference in tubal pregnancy as one of the most prominent innovations marking the progress of modern surgery.

*Read before Western Association Obstetricians and Gynecologists, 1892.

Early in the history of all surgery it is difficult to establish a procedure —perfecting the surgery of any particular operation is easy and simple as compared with the educational effort needed to establish it. As yet some procedures or operations largely practiced by eminently successful operators are questioned by the so-called conservatives.

I would urge the opinion that tubal pregnancy is a grave, perilous trouble from the very instant of its inception, and from the instant of its first recognition there should be no suspension of the vigil over it. These cases burden every physician into whose hands they fall with untold anxieties and doubts. Consultations for suspected intra-uterine pregnancy are quite common in those peculiar cases of much-attenuated uterine walls in normal gestation, but the ectopic cases are permitted to pass through the primary rupture, recurring ruptures, almost constant pain and spurious labor, entailing impaired general health, without even a suspicion of the patient's peril. Some ten cases in my own experience have had this history. Tubal pregnancy is dangerous throughout its existence. The subject is never safe until surgically relieved, and the time for this relief is when the trouble is first recognized.

*Exceptionally*—if *ever*, is the trouble recognized before rupture. The few cases recorded have all been by men with one experience, with very little knowledge of the murderous troubles found in the pelvis. A few surgeons, with an experience of nearly one hundred sections for ruptured tubal pregnancy, have never found one unruptured. Dr. Berry Hart, who has given the subject very patient and studied investigation and who discusses it from a high surgical standpoint, is worth quoting here: "As all know, the Fallopian tube is in the vast majority of instances the starting point of extra-uterine gestation; the most common result of this is that rupture occurs, usually at the second month, through some part of the tube covered by peritoneum, a result almost nuiversally fatal if left alone, and as invariably curable if operated on in time by abdominal section." An element of the history connected with these cases is that few of them are kept under observation with the definite purpose of removing the viable child at the period of spurious labor—but few are recognized at that time; alarming symptoms develop and subside, and consultation with a specialist, if he is at any time consulted, follows the death of the child, it rarely antedates it. Then all the conditions are found greatly aggravated by delay or neglect, or that which is infinitely worse, than either or both, inexcusable ignorance. The occurrence of ectopic pregnancy is regarded in widely different lights by the theorist, and by the surgeon who has learned to deal with it practically and who has accordingly come to understand the manifold directions in which speedy disaster may troop down upon unfortunate women subjected to this calamity. The argument that many cases get well of themselves, in the presence of the multitude of disasters and in the light of the horror of some of these very recoveries, is so puerile that the surgeon of practical and positive bent cannot regard them with complacency, nor consider that those who advance them have authority from which to speak more positive than the vaporings of fancy.

To explain the reasons for this apparently rather rude statement the following *causes of death* maybe enumerated:

*Hemorrhage, Peritonitis, Septicæmia, Perforation of important viscera by bone.*

For rupture of the sac in the early stages little or nothing was done till recent times. Baneham, of Virginia, did two operations, one 1790 and the other 1799, both successful. There was a lapse of one half-century before the procedure. In 1849, Dr. Harbert, an American surgeon, first suggested operative treatment for this terrible accident; but little attention was paid to his proposal till 1866 and 1867, when Dr. Stephen Rogers, of New York, wrote and urged operation. No headway was made, however, until Tait, in recent years, took it up and by a remarkable series of successes placed it at the front of major life-saving procedures.

I can only allude briefly in discussing this subject to the more important points still under discussion; those not yet settled to the satisfaction of many by the logic of experience and result. I am convinced by my own surgical experience that ectopic pregnancies are always tubal—that they rupture and end in some variety of intra-peritoneal mischief. The embryo

escapes at the first rupture and is either found or lost by digestion. Recurring hæmorrhages are common; the placenta and its traces are irremovable. I have removed a large number of fetuses, from eight to ten weeks old, dead, macerated, and largely digested, with a well-developed placenta living and growing, the growing going on long after the death of the fetus. Mr. Tait alludes to over eighty cases of intra-peritoneal hæmatocele, and in every one of them the cause was ruptured tubal pregnancy. With an experience of eighty-three sections for ectopic pregnancy I remain in surgical ignorance of extra-peritoneal hæmatocele, not a single case did I encounter. Speaking purely from my own experience I am driven to say that there is no such a thing as a pelvic hæmatocele, except those produced by ruptured tubal pregnancy. I may be classed as an enthusiast for operation, but I always find large quantities of blood and clot in the peritoneal cavity and commonly a fetus. The answer as to the proper time for surgical interference is, when you are sure rupture has taken place and hemorrhage is going on; when the symp toms are sufficiently marked and positive to justify the specialist or general practitioner in opening the abdomen for relief from such a calamity. The diagnosis should not be uncertain; the physician should be familiar with the characteristic symptoms; if not familiar he will be impressed by their precise nature, so rare is it that he has an opportunity of contending with such marked symptoms. They may be summarized as—history of pregnancy; one or more periods absent; agonizing pain; patient becomes faint and blanched, and manifests peculiar mental disturbance; symptoms of concealed hæmorrhage, and common sense would suggest at once the staying of the hæmorrhage by seeking the offending vessel. Taking time to consider the case in all its varied aspects, waiting on later developments, commonly results in needless delay and loss of the patient. Precise diagnosis is not important in the presence of a pelvic or abdominal tumor behaving badly and destroying your patient. I insist upon primary operation in all cases. The dangers of non-interference, primary and secondary, are too great and well-known for us to withold our hands. Recurring hæmorrhages, sepsis, peritonitis and exhaustion do occur in all cases of delay.

Probably the most puzzling and difficult question to settle, where interference is required, is that of dealing with the placenta. When detached, or easily detachable without much hemorrhage, it should be removed. This has been done frequently with success, yet cases have been lost through attempts to peal off the placenta. There are yet other methods of procedure—one to leave the placenta and drain the sac; another to cut off the cord, leave the placenta and close the sac. Hemorrhage may occur in either procedure, and also when the placenta is not removed. In all cases the risks of bleeding are considerable. Hemorrhage though has been rendered less alarming and fatal by our better methods of suppressing it—firm sponge or gauze packs, the use of heat or solution of iron. I will add here that iron will favor fecal fistnla and tedious convalescence. Ligatures and forceps cannot be used about viscera with safety, drainage with pressure will be the safest and surest. I am contrained to conclude from my own clinical experience that the old and non-surgical rule of leaving the placenta to slough away is too dangerous and pro longed to be practiced. The placenta should be removed in every case, or washed and hermetically sealed, thus favoring its healthy digestion and avoiding gangrenous suppuration and detachment.

Good surgery must settle the few remaining points. Secondary rupture of broad ligament, discharge of placenta and fresh adhesions, or the second implantation or grafting of the placenta, have never occurred in my experience; nor have I any knowledge of such cases except that conveyed through the literature of the subject, where they appear in large numbers. In the matter of methods, such cases are not of the kind in which you can indulge in indecision; they will brook no delay in your determining what to do and how you will do it. If there be present a bulky placenta, living and growing, either before or after the death of the fetus, the choice of one of two methods must be made and practiced with rapidity and courage—cleansing and hermetically sealing the placenta and abdomen, trusting to absorption, or secondary operation for its removal in the event of its behaving badly. The removal of a growing and

about universally attached placenta is one of the most startling and difficult procedures in surgery; it taxes the highest courage. The hemorrhage is profuse and alarming, and sometimes uncontrollable; the contraction of all tissues to which it is attached simulates very much that of uterine tissue. Rapid separation, heat and firm pressure will commonly succeed in controlling it. As to the choice of time for operation, after a careful study of the history, surgical procedure and results in the recorded cases, united with my own experience, I am strong in the conviction that there is but one safe choice, and that is prompt removal when the accident is first recognized. Delays at any period of ectopic pregnancy are dangerous.

I scarcely think it is wise to risk the mother's life for a living child by waiting for viability. Here comes in a very important question—one upon which there is a wide difference of opinion. From the standpoint from which I view the matter, the mothers life should be paramount, the child's a secondary consideration. I will not assume to discuss the question from an ethical standpoint, but confine myself to cold surgery and to results—to the matter as it relates to the mother personally and involves her relations to her family and to society. Happy, if preserved life be the fortune of both, but if there must be a loss and a saving of one I would have the saving that of the mother's.

Whatever the verdict may be ultimately as to the time of operating, the method and site for incision seem to be fixed. The method of evacuating the liquor amnii has been followed by such doubtful and calamitous results that it is now practically abandoned. The vaginal method of extirpation of the sac is also now almost universally condemned and can only be thought of in the rarest possible conditions. I can do no better than to quote Dr. Herman's conclusions, which are as follows:

1. The operation of opening an extra-uterine gestation sac by the vagina early in pregnancy, before rupture has taken place, by the cautery, knife or otherwise, is a dangerous and unscientific procedure. Abdominal section ought always to be preferred to this.

2. Soon after rupture has taken place, when interference is called for to arrest hemorrhage, abdominal section is more liable to succeed than vaginal.

3. When rupture has taken place, and the effusion of blood is followed by pyrexia, the indications for incision of vagina are the same as those in hematocele from any other cause.

4. At, or soon after full term, before suppuration has taken place, there may be conditions which indicate delivery by the vagina as preferable to abdominal section. These are—

5. When the fetus is presenting with the head, breach, or feet so that it can be extracted without altering its condition.

6. When it is quite certain, from the thinness of the structures separating the presenting part from the vaginal canal, that the placenta is not implanted on this side of the sac, and it is not certain that the placanta is not implanted on the anterior abdominal wall.

7. If the child cannot be delivered by the vagina without being turned abdominal section should be performed.

The statistics in these cases are interesting and valuable. Their chief lessons are the perils to life and the importance of prompt surgical interference. The eminence of Mr. Martin, of Berlin, gives the weight of high authority to his observations. He reported the results of his observations in 56 cases of ectopic gestation, at the recent International Congress at Brussels. We extract from a synopsis of this report published in the *American Journal of Medical Sciences*; "Most cases of ectopic pregnancy terminated in tubal abortion within the first three months. Martin's table shows that 15 terminated in the first month, 13 in the second, 11 in the third, 7 in the fourth, the remainder occurring before the ninth month. The fœtus attained viability but once in his cases. The interruption of ectopic pregnancy usually occurs from failure in the physiological conditions existing between the ovum and the cavity containing it. The pain which occurs at tubal abortion is caused by the passage of blood through the tube. The newly developed blood vessels burst, while the strongly developed muscular layer of the tube is not ruptured. Thus many cases result in spontaneous recovery. Convalescence, however, is prolonged, and there is danger of death from shock, hemorrhage, and the development of sep-

tic infection. Localized pelvic peritonitis is also common. Martin quotes Schauta's collection of 241 cases in which the ovum was not removed by operation. Of these, 128 ruptured into the abdominal cavity with bleeding; in 22, a hæmatocele formed with peritonitis. In 34, rupture occurred into the intestine; in 9, into the bladder; in 5, the abdominal wall was perforated; in 4, the vagina was entered; in 6, the ovum escaped through the uterus; in 4 cases it became incarcerated with ileus; and in 9 cases lithopædion was formed without especial annoyance to the patient. He had personally observed 5 cases in which rupture occurred, which were not treated by operation; all of them perished. The symptoms of ectopic gestation embrace some of those of normal pregnancy, early in the case, symptoms of peritoneal irritation predominate. Menstruation is disordered, hemorrhage finally ensues; during the first three months, a probable diagnosis can be made. A positive diagnosis of rupture is made by pain and collapse with profound anæmia. The child is usually not considered in the question of prognosis or operation; the prognosis for the mother, when the cases proceeded without operative interference, he found to be 68.8 per cent. mortality and 31.2 per cent. recovery. In 585 cases in which operation was performed, 76.6 per cent. recovered and 23 per cent. perished. Martin had enlarged Schauta's table and found that in 265 cases treated expectantly, 36.9 per cent. recovered, and in 515 cases operated upon. 76.7 per cent. recovered. His belief is that operation is invariably indicated. The morphine treatment of Winckel is not indorsed, nor the treatment by electricity; the ovum should be completely removed; when the fœtal sac cannot be completely extirpated, it may be stitched to the abdominal wall or punctured and drained through the vagina."

It would be very difficult to find statistics of many of these "spontaneous recoveries to which Dr. Martin refers—nor is there anything in the experience of Mr. Tait, myself and others to fortify a faith in these miraculous recoveries. Dr. Martin's own statistics and his strong statements as to the fatality of these cases, where not early interfered with, goes to disprove many such recoveries. It is admitted that even where spontaneous recovery does occur, convalescence is prolonged and there is danger of death from shock, hemorrhage and the development of septic infection. Localized pelvic peritonitis is also common. These facts leave little room for the frequent occurrence of such recoveries.

*Summary of Cases* (not including my own):

247 operative cases—
206 recoveries ..... —82.75 per cent.
41 deaths ..... —17.25 "

132 palliative and expectant cases—
62 recovered ..... —49.97 per cent.
70 died ..... —50.03 "

102 cases—
21 no operation; no treatment; fetus *quiescent* throughout life ..... —20.58 per cent.

112 cases—
Section operation ..... 112
Expectant treatmeat ..... 0

186 cases—
Section operation ..... 119
Expectant treatment ..... 67

102 cases—
Section operation ..... 16
Expectant treatment ..... 65
No treatment ..... 21

400 cases—
Section operation .....247, — 61.75 per cent.
Expectant treatment .....132, — 33. "
No treatment; quiescent ..... 21, — 5.25 "

*My own Cases:*

83 cases—
Recoveries ..... 80, — 96.39 per cent.
Deaths ..... 3, — 3.61 "

These added to other operative cases:

326 operative cases—
Recoveries .....282, — 86.51 per cent.
Deaths ..... 44, — 13.49 "

---

All One to Cabby.—It must be trying to a great personage to have his claims to distinction all unknown; but, however trying the situation, he had best be cautious about attempting to set it right. A Scottish gentleman learned this by experience.

He had a dispute with a London cabman over an eighteenpenny fare. He had offered a shilling only, and the cabman had remonstrated with him.

Drawing himself up with dignity, he said,—

"Eh, mon, but I think ye dinna ken whom ye're speaking to! I'm the MacIntosh!"

The cockney was not properly impressed: he retorted sharply,—

"I don't care if your the Humberella: I mean to have that sixpense!"—*Youth's Companion.*

# CLINICAL LECTURES.

## CORRECTION OF SYPHILITIC DEFORMITY OF NOSE; SYPHILITIC STENOSIS OF LARYNX; AMPUTATION OF LEG ON ACCOUNT OF COMPOUND DISLOCATION OF ANKLE; TORTICOLLIS COLLAR; REMOVAL OF BREAST FOR CANCER.

ROSWELL PARK, A. M., M. D., Buffalo. N. Y.

Here is a lad upon whom I operated last week. The operation was an experiment, proposed and accepted as such, with the hope of relieving a deformity which goes by no particular name but which consists in an absence of the bridge of the nose. This deformity is usually the result of hereditary syphilis and I presume that it is in the present instance, though the history and other confirmatory evidence is lacking. The boy works in an architect's office and has imbibed ideas of symmetry which have led him to seek an improvement of the shape of his nose. The operation consisted in making a small longitudinal incision on each side of the nose and separating, by means of a small chisel, the nasal bones from the nasal processes of the superior maxillary bones. The nasal bones were then pried upward and forward and held in place by a hare-lip pin, after drilling both bones and the nasal septum which, at this level, is the vertical plate of the ethmoid. Lead plates prevented the hare-lip pin from slipping inside the nose. The plates and pin will not be removed for a few days yet. The operation amounts to producing a compound fracture, and time must be allowed for the formation and organization of the blood clot so as to afford a firm foundation for the displaced bones. The patient expresses himself as satisfied with the result and you can see that his nose has a very good shape.

---

This patient illustrates the evil results of tertiary syphilis when treatment is not properly persisted in. Two or three years ago, he was treated in this hospital during the secondary stage of the disease but left before he was sufficiently medicated and returned later for treatment in the tertiary stage. There is scarcely an area on his body as large as the palm of the hand, where there is not the scar of a syphilide which has previously ulcerated. Last winter he developed a syphilitic laryngitis which became more and more chronic and proliferative, and one night the obstruction increased so rapidly that I was called by telephone about midnight to do tracheotomy. The emergency was so great that I believe a delay of five minutes would have resulted in the man's death. He is a very good patient in the hospital and obeys directions implicitly, but when he goes out he neglects to take his medicine and report for observation and he has paid dearly the penalty for his carelessness. He wore the trachea tube for so long a time that the larynx filled up completely with fibrous tissue, and he was unable to speak even in a whisper although he could form the words with his lips and blow through the trachea tube. Only those who were familiar with him could understand what he tried to say, and he oftened had to resort to writing to make himself understood. Some time ago I divided the thyroid cartilage in front and succeeded in reaming out the laryngeal passage. It was not so easy to keep the passage clear on account of the tendency to proliferative granulation and cicatricial contraction. The operation, therefore, was repeated in your presence. By removing some of the tissues and dividing others, I finally made an opening into which I could insert a tube, but I did not want to remove the trachea tube for fear that he might need to breath through it again. I therefore had a hole cut in the convexity of the trachea tube through which a smaller tube was slipped upward to communicate with the pharynx. He thus has an improvised artificial larynx through which he can breath and which allows the use of the lower tracheal opening if, through any accident, the upper passage should become clogged. He wears a cork in the trachea tube and is satisfied to talk in a whisper. At considerable expense, an

artificial larynx could be made with a vibrating reed to imitate the sound of the vocal cords. But the patient can not go to the necessary expense and it is by no means advisable that he should. I had one patient who discarded an elaborate artifical larynx because the monotonous and metallic sound of the reed made him too conspicuous and he thought it preferable to speak in a whisper.

---

Five or six weeks ago, a German, aged forty-five, slipped in getting off a street car and sustained a compound dislocation of the right ankle with a little chipping of the end of the fibula so that the external lateral ligament was loosened. He was taken to the Fitch Accident Hospital and treated expectantly, the part being kept immersed in a hot antiseptic solution. The idea was to afford an opportunity for recovery without the loss of the foot but with a stiff ankle. The case, however, has not done as well as might have been expected, sloughing has occurred and the joint surface is widely exposed. The case calls for some interference, possibly an atypical resection, perhaps a removal of the astragalus and the diseased soft parts ; possibly amputation will seem advisable. The patient is a poor laboring man whose time is his only bank account. If I resect the joint, it will be at least six months before he can use the foot, while after amputation he can be about in a few weeks. I have presented the alternative to him with considerable hesitation, because the foot looks as if it might be saved if ample time were allowed. Still the patient understands that he can have a useful artificial foot attached to the stump, so that he will be practically as well off as if resection were successfully performed. I begin the operation, therefore, with the full consent of the patient to resect or amputate as seems better, not with the injunction so frequently given, to save the member at any sacrifice of time or expense.

On examination the tissues are soft and grumous, there is much infiltration about the sloughing surface and I remember that after the injury there was a cellulitis extending up the leg. I shall, therefore, amputate. The line selected is four inches above the malleoli and I will use the circular method. It will not be wise to close the tissues of the stump as closely as in the amputations which you saw last week, for there is still some bogginess left from the cellulitis and I should feel safer to leave provision for drainage.

---

This is the little boy upon whom I did a tenotomy of the sterno-cleido-mastoid for torticollis. Although the obstacle to the natural position of the neck has been removed, the faulty habit remains and something is necessary to straighten the neck. If the child were to go among intelligent people, a series of exercises could be directed for this purpose, but he is leaving the hospital for associations in which we cannot rely upon help from others and some mechanical aid is necessary. I have therefore devised this plaster-of-Paris collar which is held in place partly by bandages partly by its own weight. It is not as elegant in appearance as a collar made of steel and leather, but it is inexpensive, the raw material costing perhaps five cents, and it will answer the purpose perfectly. It is made heavy and strong, for we do not expect to see the boy again for two or three weeks and I want the collar to be practically unbreakable.

---

The patient for whom we have been waiting, is a woman of sixty-seven who looks seventy-five. She belongs to that social class which has nothing before it but work, and she is thin and worn but still perfectly well so far as general health is concerned, and rugged. Five months ago she fell on the handle of a parasol and bruised her side and soon after, a lump appeared in the left breast, which has steadily augmented in size and has become more and more adherent to the overlying skin, until it is now firmly attached to it and the skin is reddened but without tenderness or heat or other sign of inflammation. Only by firm pressure can I cause any sense of discomfort in the tumor. The history and absence of local signs enable us to exclude acute inflammation. If this were an abscess, there would be the history of previous inflammation and there would now be fluctuation, which can not be detected. The mass is certainly a neoplasm in every sense of the word; but is it benign or malignant? The woman is at an age when such benign tumors of the breast—never very common—are quite rare and when malignant tumors are frequently found. There is close adhesion

with the skin, whereas a benign tumor would simply push the skin before it. The nipple is not retracted. One sign of malignant disease is lacking,—the enlargement of the lymph nodes in the axilla, but they may be slightly involved without being palpable through the skin. There is but one indication for treatment, the removal of the breast. Its functional activity ceased more than twenty years ago, and there can be only the vestiges of glandular tissue left. It is on this account that retraction of the nipple is not manifest. The great differences in the apparent size of mammary glands are due to the accompanying connective tissue and fat. Except in the matter of age, we are taking this case at a favorable time, for the lymphatics are little if at all involved.

I make the lower incision first so that the blood will not obscure the field of operation. You will notice that I include the nipple for, although the tumor does not appear to involve it, common sense dictates that all the glandular tissue in which the disease originated should be removed. Having taken out the breast, our next duty is to clean out the lymph-nodes in the axilla. Even if they are not enlarged, it is now held to be the only proper course to remove them for the purpose of future security. I consider that on the thoroughness of this part of the operation depends the exemption from a renewal of the disease in her case. Here is an enlarged lymph node which could not be felt through the skin. It shows how necessary it is to include the axilla in the field of operation in every case. The next step in the operation is the tying of the vessels which have been cut, among them the long thoracic artery. The wound is then sprayed with hydrogen peroxid solution. You will notice that the only part of the wound in which there is any chance for retention of fluids, is high in the axilla and I will insert a decalcified bone drainage tube here which will serve as a conduit for twenty-four or thirty-six hours, and will then collapse and be absorbed later. In making the counter-opening for this tube, I have tried to avoid the latissimus dorsi, but have been obliged to pierce it. The wound is now closed with cat-gut and covered with iodoform and antiseptic gauze. It is important to keep the arm absolutely still. I, therefore, apply a pad of cotton over the ordinary dressing, flex the fore-arm across the chest and bind the arm to the body by the triangular application of the roller bandage.

---

He Got the Whisk.—Mr.——had a new office clerk, who was recommended to him by the ladies of the W. C. T. U. for his strict temperance principles, which were exactly in accord with those of Mr.——himself.

"Peters," said Mr.——to the new man yesterday morning, "take some money from the drawer and go out and buy me a whisk."

"Trimmed or plain, sir?" asked Peters, with a glad, joyous look in his eyes.

"Plain, of course; the plainer the better; something solid and substantial."

Peters was gone about half an hour. When he returned he carried a big, thick tumbler in his hand full of a dark red liquid. His voice sounded as if he had caught cold.

"Here's your whisk," said Peters,, setting the decoction down suddenly in front of Mr.——.

"Good heavens, man, what is this?"

"Whisk, whisk, that's what," said Peters, mysteriously.

"But I wanted a whisk-broom."

"Why didn't sha sho? Thought it was 'breviation for whiskey. Nemmer mind, it won't be wasted." And he swallowed it on the spot.

Peters is again looking for a place. —*Detroit Free Press.*

---

Ma's Shoe-Strings.—Susie's mother sent her to the shoe-store the other day for some shoe-strings. The little girl tipped the door-latch and slowly walked up to the proprietor.

"Mamma sent me down for a pair of shoe-strings," and Susie fingered her money nervously as she looked into the dealer's face. The latter turned to a bunch of strings upon the wall and began to pull a couple out. Then he stopped.

"How long does she want them?"

Susie looked flustered. "I don't know, but I think mamma wants them to keep." —*The Wasp.*

A Precarious Existence.—He—"No, the boss doesn't pay me more than I'm worth."

She.—"How in the world do you manage to live on it?"—*Lippincotts.*

# COMMUNICATIONS.

## CONTRIBUTIONS TO THE STATISTICS OF RENAL SURGERY.*

DR. JAMES ISRAEL.

By primary nephrectomy the author understands the immediate removal of the kidney during the first operation; by secondary, the removal of the kidney on which nephrotomy had previously been tried. He places stress upon the high mortality of the secondary, in comparison to primary nephrectomy: three cases out of four were lost where secondary nephrectomy was done. One death was due to iodoform poisoning; in the other two cases the primary operation would undoubtedly have given better results. One of these cases suffered from pyonephrosis, for which nephrotomy had been performed seventeen months before, leaving a fistulous tract to the kidney; the urine was clear at first, but gradually retention pockets formed in the operated kidney, which persistently returned in spite of the dilatation of the fistula; and fourteen months after, a swelling of the other kidney could be demonstrated. Uræmic attacks followed so that seventeen months after the nephrotomy, nephrectomy became necessary; the patient died eight days after the operation. The specimen showed extreme lipomatous changes, leaving only slight traces of kidney substance, the ureter was also surrounded by masses of fatty tissue. The third patient succumbed on account of extensive pathological changes in the other kidney.

The author advises, from the experience of these cases, primary extirpation of the kidney, even where the other be slightly diseased, as the patient has more chances for entire recovery.

He proposes, if the operation is necessary on one kidney, to do the primary operation, even if the disease has attacked both kidneys.

In suppurating processes of the kidney, he also advises prompt and primary nephrectomy; should the kidney be filled with abscesses leaving but small portions of its parenchyma, so necessary for the uses of the human economy, it has been deemed proper to leave that parenchyma, so far as possible, intact, until satisfied as to the condition of the other kidney.

If primary nephrotomy has been made and, at a later date, it is demonstrated that the second kidney is normal, it is necessary to perform nephrectomy of the first as quickly as possible.

The study of the condition of the second kidney is, in spite of various methods given, often very difficult. The author proposes in certain cases, to ligate the ureter of the affected kidney, which will give a certain amount of information as to the condition of the second.

The author presents, in a critical manner, the results of his renal operations. In those operations classed as primary, death occurred thrice. One patient, a female, was 56 years old, with a carcinoma of the right kidney. The first symptoms were noticed ten years before consultation; the left kidney seemed normal. The operation was easy and rapid, but death resulted in forty hours from vomiting and meteorism. The autopsy proved a normal condition about the wound; there was brown atrophy of the heart; in the left kidney a slight parenchymatous cloudiness could be detected. In a fatal case of nephro-lithotomy, the same condition was found. The author makes the important statement that no chemical solutions, iodoform, sublimate, etc., had been used. It was thought that possibly chloroform narcosis of long duration may have acted upon the kidneys.

In seventeen operations without complications, fourteen cases presented a slight affection of the remaining kidney, as albumen, hyaline and cylindrical casts and red blood corpuscles, etc., had been found in the urine. The same condition was found in a nephrectomy of some standing, and in a narcosis of long duration. In the third case of nephro-lithotomy, death was caused by septic inflammation of the operated kidney produced by

* Read before the Freie Vereinigung der Chirug., Berlin, 1893, and translated by M. B. Werner, M. D.

the patient having frequently torn the drain out of the wound.

In this patient the author saw for the first time a reflex aneuria. The patient suffered for a long time from renal colic of the left side and the left kidney was enlarged and painful. These attacks of pain were often eased by sudden palpation of the kidney and the secretion of urine was immediately reinstated, and, since the right kidney seemed healthy, there appeared to be but one explanation, that of reflex aneuria. A longitudinal incision into the pelvis of the kidney demonstrated the presence of a stone (removed) which had acted, for six days, as a check valve to the ureter. Closure of the renal pelvis could be done only on the lower four-fifths; above, the capsule of fat was drawn together and sewed fast; almost immediately after the operation urine passed through the bladder and wound; after two days all the urine passed through the bladder. This was proved by endoscopic examination when directed towards the right ureter.

The production of a reflex aneuria is illustrated in the following case: A man suffered for years from an intermittent hydro-nephrosis with consequent attacks of hæmaturia; pressure by the distended cavity acted as a dam to the secretions of the healthy kidney. Puncture of the sac reinstated the flow of urine.

Another case also is explained as a reflex aneuria. In this particular patient the right kidney had been extirpated for hydronephrosis, the wound sewed and a drain inserted. The result was normal up until the sixth day, when the secretion suddenly became scant and marked pain could be traced to the location of the extirpated kidney. Considering that a portion of the drain caused pain at the stump, the drain was removed and at once there was an increase of urine and a disappearance of pain. Microscopically the urine contained a large quantity of microliths, formed probably from a central epithelial cell with an onion like covering. In the extirpated kidney small microliths of similar character could be found.

The last fatal case the author has had up to date, was a woman suffering from painful right-sided renal colic, in whom, though palpation was negative, incision was considered necessary for diagnosis. There was nothing found abnormal; the rather large wound of the kidney was closed by deep and superficial catgut sutures, and a compress bandage ended the operation. Soon after the operation, vomiting set in, tympanites and increased pulse. On the second day the bandage was taken off; the fifth day colotomy was performed but without success. The autopsy revealed a small intestine greatly distended; in the large intestine, a stagnating fecal accumulation; beneath this a contracted portion with slight bloody effusions; there was a similar condition found at the colon transversent in the region of the right flexura. The author expresses his opinion that the unfortunate result was probably due to the decided compression of the bandage, which had produced irritation of the nerves of the intestines. He has, therefore, returned to the belief that renal bleeding can be controlled by manual compression, after the closure of the wound by deep catgut sutures. As a proof he mentions one case in which the kidney had been completely cut in half, the bleeding being arrested later on by several deep, and a few superficial catgut sutures.

| OPERATIONS. | No. of cases. | Deaths resulting from operation. | Percentage |
|---|---|---|---|
| Primary Nephrectomy | 29 | 3 | 10.3 per ct. |
| Secondary Nephrectomy | 4 | 3 | 75 per ct. |
| Nephrotomy | 11 | 1 | 9 per ct. |
| Opening down to the entire ureter and Pyelotomy | 1 | 0 | 0 per ct. |
| Nephro-lithotomy | 5 | 2 | 40 per ct. |
| Nephrorhaphy | 3 | 0 | 0 per ct. |
| Exploratory abdominal incision down and into the kidney reaching the pelvis | 4 | 1 | 25 per ct. |
| Puncture of the capsule Propia | 1 | 0 | 0 per ct. |
| Drainage by Puncture | 2 | 0 | 0 per ct. |
| Exploratory incision of the kidney with shelling it from its capsule fat | 3 | 0 | 0 per ct. |
| Closure of a fistula from the kidney by operative means | 1 | 0 | 0 per ct. |
| Incision for Perinephritis | 7 | 0 | 0 per ct. |

# HEART-DISEASE OR KIDNEY DISEASE?*

JAMES TYSON, M. D.†

I have myself so often been mistaken in the first conception formed of the relation between a combination of symptoms for which heart or kidney may be responsible, and have so frequently had occasion to share the difficulty with others, that I have been forced to give the matter some thought; and it seemed to me that so practical and important a subject might also be interesting to the members of this Society.

The difficulties met under these circumstances will, I think, be better appreciated by the brief story of four or five illustrative cases:

CASE I.—O. E., a shop-girl, aged fourteen, was admitted to the Hospital of the University of Pennsylvania, October 31, 1892.

Her mother is said to have heart-disease, but the family history is otherwise negative. The patient herself had measles in childhood, but, with this exception, reported no illness until that for which she sought admission. This set in apparently only three weeks previously, when she noted that her legs were swollen. Shortly after this she became short of breath. She continued, however, to perform the duties of her position up to the time of her admission to the hospital.

On admission, her appearance was most striking. A lustrous pallor pervaded her entire body—in fact, she presented the characteristic waxy hue of chronic renal disease. Her feet and legs were much swollen, as were also the right hand and face. To a less degree she was everywhere edematous, though more so on the right side, on which she mostly lay. The urine was dark-hued, had a specific gravity of 1030, was loaded with albumin, and contained numerous granular casts.

My colleagues, as well as myself, all said a "typical case of renal disease." The urine examination seemed scarcely necessary. The diagnosis could be made at a glance. As a matter of course, however, her heart was also examined. The apex-beat in the fifth interspace was forcible and rapid, from 108 to 120, while the respirations numbered from 40 to 43 in the minute. On palpation, a cardiac thrill, systolic in time, could, in addition, be appreciated.

Percussion determined the upper border of cardiac dullness to the left of the sternum, at the superior edge of the third costal cartilage; the right border one inch to the right of the right margin of the sternum, There was, therefore, enlargement of the right side of the heart, as well as of the left. There were the signs of pleuritic effusion on both sides. Auscultation recognized a double murmur, most intense at the apex, with the systolic portion conducted into the axilla.

Here was a case of mitral disease—regurgitation and probably stenosis with right-sided dilatation; but the intense waxy appearance and the pronounced albuminuria led us to believe that there was also positive renal disease, probably subacute parenchymatous nephritis.

The girl was ordered absolute rest in bed, five minims of tincture of digitalis three times a day, and caffein citrate three grains every four hours. Copious diuresis set in, and at the end of five days the dropsy was almost totally gone. The scanty urine had increased until it had reached 62 ounces, while the albumin and the casts had entirely disappeared. The change was almost incredible. I had never seen such a striking one in so short a time. The mitral murmur continued showing that the heart disease was the permanent one, and the idea, almost irresistible at first, that there was some special form of renal disease, independent of the passive congestion due to the cardiac disease, was dissipated.

She remained in the hospital until December 24. Once there was a return of the albumin and a few granular casts, concurrent with an attack of bronchitis, but these again disappeared, and she was discharged seemingly quite well. The diastolic part of the double mitral murmur finally also disappeared, and the heart had been restored to its original dimensions, but the mitral systolic murmur continued, and is likely to be permanent.

*Read before the Pennsylvania State Medical Society, 1893.

†Professor of Clinical Medicine in the University of Pennsylvania, etc.

Case II.—F. R. P., a bank-officer, aged forty-two, was seen in consultation with Dr. S. R. Crothers, of Chester, Pennsylvania, on November 19, 1892. With the exception of typhoid fever, ten years before, and an attack of influenza in December, 1891, he had never been seriously ill. About one year previously to his visit to me, he first began to have attacks of palpitation of the heart and shortness of breath, with headache. He was treated for "functional trouble," and improved sufficiently to return to work. In this, however, he overtaxed himself, and at the end of about two months he was again compelled to give up. Although he spent much of the summer at the seaside, there was not improvement sufficient to permit his return to business. All of this time his symptoms pointed to heart disease, and his own belief and that of his family were that this was his principal, if not his sole illness.

At the date of his visit to me there were aggravated dyspnea and cough, but the headache, from which he had before suffered so much, had disappeared. There was also nausea, especially in the morning, but at times also early in the day, associated occasionally with diarrhœa. His complexion was intensely shallow — almost cachectic.

On inquiry I found that his feet were a little swollen at night, but that this swelling disappeared each morning. Examination of his heart disclosed enormous hypertrophy of the left ventricle, the apex being lowered and displaced to the left. The aortic second sound was accentuated, but there was *no murmur*. The action of the heart was tumultuous, its rate frequent, its rhythm gone.

The urine throughout has been copious, light-hued, and low in specific gravity, until a short time before his visit, when it had become scanty and high-colored; but at the time of his visit, through the action of diluents and diuretics, it was increased to 64 ounces in the twenty-four hours. A portion of this examined by me had a specific gravity of 1012, and contained only one-twentieth per cent. of its bulk of albumin and a small number of hyaline casts.

In this case the prominent symptoms were cardiac, in contrast with Case I, in which the most striking symptoms pointed to the kidneys as their source, and in fact were at the time caused by renal complication. Yet the former was primarily a case of renal disease.

This is a state of affairs that supervenes on an interstitial nephritis, a gradual hypertrophy of the left ventricle, the rationale of which is not perfectly agreed upon, but which I am inclined to look upon as a compensatory hypertrophy, maintaining the individual in tolerably good health until compensation begins to fail, when the symptoms of cardiac distress described set in, and increase until death takes place, as in this case, suddenly, from simple cardiac failure, or, as is perhaps more frequent, from uremia.

In this instance, therefore, a case of primary renal disease was overshadowed by cardiac symptoms in so marked a degree as to cause the latter to be overlooked.

Case III.—A. G. B., a retired merchant, aged sixty-two, consulted me first on the 16th of April, 1892. He had a clear family history of gout, his father being gouty years before his death, and dying suddenly. The patient himself had been subject to attacks of gout for a number of years, and had cretaceous deposits in his knuckles. He had an attack of influenza in the early part of 1890, and another in May, 1891; but during the year previous to his consulting me, he had been more than usually exempt from gout.

Albuminura was discovered by Dr. Pepper in May, 1891. Following this the patient spent the summer in Europe. While in Europe the albumin disappeared, and continued absent until a few days before he consulted me, when its presence was discovered by his son, a medical man. He also noted at this time a little dyspnea on exertion, but with these exceptions felt as well as usual. His last evident attack of gout was on board ship, in the autumn, while returning from Europe.

At the time of his visit to me, in April, 1892, I examined his urine, morning and evening samples. Each contained one-tenth of its bulk of albumin, but I found no casts in either sample. The morning urine had a specific gravity of 1016; the evening, of 1014. I concluded promptly that I had to do with a case of chronic interstitial nephritis of gouty origin.

In June following his visit to me, the patient again went to Europe, and returned

late in September, 1892. He had a couple of slight attacks of gout during his absence, and a little oppression in breathing on shipboard, so that he had to sit up in his berth. During the month of June there was some irregularity of action of his heart, which he ascribed to flatulence. With these exceptions, he considered his health even better while in Europe, in the summer of 1892, than in the previous summer.

On November 21, 1892, he again consulted me. He complained of flatulence, and of what he termed wind pressing on his heart. This prevented him from lying down in comfort. He also thought that it caused cough. On the day before his visit he first noted a little swelling of his feet.

I now examined his urine again. It was darked-hued, contained one-tenth of its bulk of albumin, and this time I found a few hyaline casts. There was also a little swelling about his ankles, and auscultation disclosed an evident mitral systolic murmur. I prescribed rest at home (he had been attending to some business), salicylic acid, pepsin, and aromatic powder; for the flatulence, also hot water before meals; and for the dropsy, a pill containing digitalis, quinine, squill, and nux vomica. In a few days the edema had disappeared, and the dyspnea was partially relieved. A few days later both symptoms returned, and although again relieved for a time, they proved ultimately intractable. There was dulness to the right of the sternum. Evidently the right ventricle was yielding. The urine became more scanty, the albumin increased, as also did the cast, and the patient died suddenly December 20.

Case IV.—John W., a colored laborer, fifty-two years old, was admitted to the Hospital of the University of Pennsylvania, April 18, 1893. His family history was negative. He had had a bad attack of typhoid fever thirty-five years ago. Eight years, ago, while working in a brick-yard, he suddenly fell, and was unconscious for about four hours. With returning consciousness came unimpaired muscular power; but four years later he awoke one morning completely paralyzed on his left side, without any evidence of anything else happening in the night. At the end of three days, however, he began to regain power in the arm and leg of the affected side, and in three months was able to move around with the aid of a cane.

His condition in this respect has been improving steadily, but two years ago he noted that he was short of breath, and last winter this symptom grew worse, while edema of the legs was superadded. These symptoms finally became so aggravated that he entered the Philadelphia Hospital, whence, after six weeks, he was discharge, greatly relieved.

Two weeks previously to admission to the University Hospital he again became ill, the chief symptoms being enormous swelling of the legs, orthopnea, and a dry, hacking cough, very troublesome at night. On admission we noted also irregularity of the heart, hypertrophy of the left ventricle, and an easily recognizable mitral systolic murmur. There was also the remant of the left-sided paralysis, and on this side the edema was much greater than on the right side. There were the signs of effusion in the left pleural sac, and the percussion boundary of the liver indicated some enlargement.

The urine was albuminous, but no casts were found.

The diagnosis here made was mitral regurgitation, a diagnosis that was thought to be sustained by the enlargement of the liver. Treatment proved ineffectual, and the man died less than three weeks after admission.

At the necropsy there was found enormous eccentric hypertrophy of the left ventricle, with dilatation of the right ventricle, both cavities, and especially the right, being distended with blood. The heart weighed 1000 grams with the blood in it—750 when emptied, the normal weight being about 337 grams. The *mitral leaflets were a little thickned, but essentially normal.* The aortic cups were normal, as were also the valves of the right side of the heart.

There was a large effusion in the left pleural cavity, as recognized before death, and a patch of congestion in the lower part of the lung. The liver weighed 1285 grams, and was *not,* therefore, enlarged, the normal weight being from 1550 to 1860 grams.

Both kidneys were enlarged, the right weighing 210 grams, the left 220 grams, the normal weight being from 130 to 150 grams. The cortices eseciaplly were widened, and the seat of chronic parenchy-

matous nephritis, which, in the light of the autopsy, I regarded as the cause of the hypertrophy of the left ventricle.

I have selected, from among many cases these four of combined cardiac and renal disease, in which there was, at the beginning, and in some throughout life, more or less erroneous conception of the exact state of affairs. The first case, that of the shop-girl, aged fourteen, was supposed to be a case of chronic parenchymatous nephritis, while further study showed it to be one of primary valvular disease of the heart, with secondary passive congestion of the kidney.

The second case was one of chronic interstitial nephritis, with hypertrophy of the left ventricle, in which all of the symptoms pointed to primary heart-disease but the true nature of which was easily revealed upon closer study.

The third case was a more complex one than either of the others. An ancestry of gout; a personal history of much gout; an albuminuria, at first small; absence at first of casts, and then sparse casts, all pointed to gouty kidney a supposition by no means weakened by the oppression and dyspnea, symptoms that almost always supervene when the hypertrophied left ventricle of chronically contracted kidney begins to fail. On the other hand, the evident mitral murmur, the moderate degree of hypertrophy of the left ventricle, the stretched right ventricle, the irregular heart, the gastric catarrh, and the dropsy, pointed to a condition of mitral regurgitation which I cannot but think was also present, a view in which I was also sustained by Professor Da Costa, who saw the case with me. Yet the problem was a difficult one, and the question, "heart or kidney?" was carefully debated. It seemed to us that in this case doubtless both were effected independently of that interdependence that always exists between these two important organs. That is, there was interstitial nephritis and endocarditis, both the results of the same cause—gout—and the cooperation of these two conditions accounted for the intractableness of the case. Unfortunately, in this case there was no autopsy to settle the question, and it must always remain a matter of probabilities.

That such a state of affairs does occur is shown by the following interesting case:

Case V..—C. K., a Russian coal-miner, aged twenty-eight, from Schuylkill County, was admitted to the Hospital of the University of Pennsylvania, April 12, 1893. On account of his total ignorance of English, no family or previous personal could be elicited, except the indefinite statement that his feet had been swollen for ten years, and yet that he was perfectly well up to three weeks before admission, and working in a coal breaker.

On admission he was gasping for breath, in an unpleasant, grunting manner. His heart was extremely irregular, and at times beat so rapidly that it could scarcely be counted. It is noted soon after admission at 144, again at 166. His respirations were noted at 36; and when his pulse was 166 the respirations were noted at 46. His temperature was normal. His belly was distended with fluid. There was edema of the feet and legs—in fact general anasarca—and he lay in such a stupid state that it was difficult to get any information from him. On admission he was expectorating a blood-stained mucous, regardless of time or place.

Physical examination revealed the liver to be much enlarged and tender; the heart not much enlarged, but acting tumultuously, and no murmur could be detected. Subsequent examination showed the right boundary of the right ventricle at the right edge of the sternum, indicating enlargement of the right heart. The examination of the lungs, on admission, was not satisfactory, because of the extreme illness of the man, and his disgusting, filthy state. The urine was scanty, high-colored, and bile-stained. It contained only a moderate amount of albumin, from one-twentieth to one-eighth of its bulk, but numerous hyaline and pale granular casts.

Under full doses of the infusion of digitalis he improved quite rapidly, the pulse and breathing rate coming down gradually. The rhythm of the pulse also improved, and the anasarca diminished. On the 30th of April his pulse had fallen to 64, and my note reads: "Although the pulse is slow and forcible, no murmur is detectable, yet we feel sure there is mitral regurgitation." His improvement was, however, so great that he was even allowed to sit up. On May 5, his temperature began to rise, and concurrently his breathing to be more frequent. On the

11th the signs of fluid in the left pleura were apparent (probably had shown themselves a couple of days earlier, because, on account of difficulties, he was not examined daily). The respirations were 50, but the pulse did not rise above 108, for the first time a distinct mitral systolic murmur was audible. On the 14th it was thought a murmur was heard, but repeated examinations, even when the heart was at its best, failed to detect anything definite until the 11th. The man died suddenly a day later.

The necropsy was most instructive. The lesions were numerous, but the most interesting in this connection was the association of extreme mitral stenosis, in the shape of a button-hole mitral orifice, and a pair of typical large white kidneys, beginning to undergo contraction. There was also enlargement of the heart, more especially in the direction of the right ventricle, as recognized before death, associated with marked dilatation of the left auricle. There was a left-sided empyema of recent origin, as shown by a fresh layer of thick lymph, probably the immediate cause of death; anthracosis, or miner's lung, with cavities; an enlarged hypertrophically cirrhotic liver; an enlarged spleen with two pyoid sacs, probably softened infarcts.

The fourth case was a complete surprise in the light of the autopsy; yet I am doubtful whether, with the situation repeated, I would make different diagnosis. The distinct mitral systolic murmur and the extreme anasarca, the scanty urine and plural effusion, all combined to favor the idea that there was mitral regurgitation, while the fact that the man had had two seizures, best explained on the supposition of cerebral embolism, of which a cardiac embolus is the most common cause, seemed to add all that was required to make the diagnosis absolute. One symptom only might have suggested a renal origin, and that was the degree of hypertrophy of the left ventricle, without aortic disease. Mitral regurgitation, while causing hypertrophy of the left ventricle seldom produces the extreme hypertrophy that attaches to aortic valvular disease or chronic renal disease without aortic valve disease. At the same time the extent of this hypertrophy was not appreciated before death, because of the difficulty of investigation occasioned by the naturally thick chest-walls further thickened by anasarcous infiltration. Under the circumstances, the mitral murmur is best explained on the supposition that there was mitral regurgitation consequent on the dilatation of the hypertrophied left ventricle.

Yet, notwithstanding the difficulties encountered in the separation of heart-disease from kidney-disease, there are certain points that, if borne in mind, aid in the discrimination. These points, already referred to, deserve, in conclusion, to be recapitulated: First, the conditions most likely to be associated or confounded are on the one hand, mitral disease and, on the other, chronic parenchymatous nephritis, and the last stage of interstitial nephritis, when the urine, from having been copious and light-hued, becomes scanty and dark-hued, because of failing cardiac power.

CHRONIC PARENCHYMATOUS NEPHRITIS.

Urine scanty and high-colored; high specific gravity; highly albuminous.

Numerous granular, dark granular or fatty casts.

Much dropsy.

No mitral systolic murmur.

As a rule no hypertrophy of left ventricle, which may, however, be present at times.

No enlargement of liver.

No signs or symptoms of arterio-capillary fibrosis.

No retinitis albuminurica.

No history of gout.

Seldom a history of rheumatism; more frequent of infectious disease.

Uremia infrequent.

Partial response to treatment.

CHRONIC INTERSTITIAL NEPHRITS.
(Last stages.)

Urine though scanty is still light-hued, and has low specific gravity; moderately or slightly albuminous.

Few casts and these hyaline or slightly granular. Often no casts.

Little dropsy as a rule, though when heart fails, dropsy may be marked.

No mitral murmur.

Always marked hypertrophy of left ventricle, except in persons feeble and cachetic at the outset; this without aortic murmur.

No enlargement of liver.

Symptoms and signs of arterio-capillary fibrosis may be present.

Retinitis albuminurica may be present.

History of gout, lead-poisoning, or free eating and drinking.

No history of rheumatism or infectious disease.

Uremia frequent.

Doubtful response to treatment.

MITRAL DISEASE.

Urine scanty and high-colored; high specific gravity; moderately or slightly albuminous; rarely highly albuminous.

Few casts, hyaline or slightly granular.

Much dropsy; effusion into serous sacs.

Mitral murmur.

Moderate hypertrophy of left ventricle; hypertrophy of right ventricle.

Enlarged and tender liver.

No arterio-capillary fibrosis.

No retinitis albuminurica.

Seldom a history of gout, alcoholism, or free eating and drinking.

Probable history of rheumatism or infectious disease.

No uremia.

Generally prompt response to treatment.

These points of diagnosis refer more particularly to uncomplicated cases. With complicated cases the difficulty is greatly increased, and the decision must be one of probabilities. A fact of great value in my judgment in favor of a primary and advanced kidney-disease, is the failure of heart-tonics like digitalis, to produce diuresis, even though the pulse-rate is decidedly reduced by the action of the remedy.

Now, what is the practical bearing of these considerations? I answer, not so much in the direction of therapeutics as in that of prognosis. For, happily, the treatment of these conditions is essentially the same, and to this subject I have given very full consideration quite recently elsewhere. In the matter of prognosis, however, it is of the extremest importance. For in cases of pure mitral disease, not too far advanced, the most favorable prognosis may be given, as evidenced by our experience with Case 1. In the stage of renal disease under consideration, however, and in the combined form with actual structural change in both heart and kidney, the prognosis is very unfavorable, and to mistake the one condition for the other, and to prognosticate accordingly, may seriously jeopardize one's reputation.

## BRONCHO-PNEUMONIA.*

J. C. H. LAWRENCE, M.D., Green Bay, Wis.

Considering broncho-pneumonia from the standpoint of immediate fatality, and also as a causative factor in later developed chest troubles, it may be classed the most grave of children's diseases peculiar to this northern country.

It has been defined as an acute inflammation of the bronchial lining membrane, which by direct extension and mechanical phenomena incidental to the disease, involves the connective tissues, bronchioles and air cells. Thus the whole lung structure may in severe cases take on inflammatory action.

There is little doubt in my mind that many of the deaths from so-called bronchitis and croupous pneumonia, are due to broncho-pneumonia. Again, it is one of the greatest complications of measles and whooping-cough, and may, in many cases, be the direct cause of death credited to these diseases. Bear in mind also, that a large percentage of all cases of pulmonary consumption have their starting-point in the disease.

Changes of temperature and humidity unquestionably influence, if not cause the disease.

It is found to be non-prevalent in families and localities where bad hygiene prevails, but seems in this latter instance to take on a more unfavorable course. Some authorities claim for it a specific origin, even having gone so far as to discover a micrococcus.

1 "The Relations between Renal Disease of the Circulatory System," International Clinics, Vol. 4, second series, 1893. "Treatment of Chronic Valvular disease of the Heart," *Therapeutic Gazette*, April 15, 1893.

* Read before the Fox River Valley Medical Society, 1893.

Probably the disease starts by an irritation of the bronchial mucous membrane, from various causes, and is developed by direct extension to the lung tissues. When it occurs as a complication of measles, extension takes place more rapidly than in the simple form, the initial stage being so short as to render it unappreciable. Notwithstanding its extremely short duration however, pus is formed in the smaller bronchioles and air cells with alarming rapidity and profuseness. Attended by whooping cough on the contrary, its advent is slow and insidious. Occurring as a distinct disease itself, the bronchial stage may last from three to ten, sometimes twenty, days.

When the lung tissue is invaded the temperature rises to 103° or 105°. The cough becomes hacking, painful and frequent. The inspiration more rapid, shallow and diffcult. The countenance takes on an anxious look as efforts to breathe become more labored. The progress of the inflammation may be extremely rapid so that all the lung tissues may be at once involved, or it may be slow and gradual, occupying several days. When large areas of lung substances collapse, temperature falls. The cough becomes less, sometimes disappears. The countenanee becomes livid, the skin cool and clammy with more or less perspiration. The distress for breath momentarily increases and unless the condition soon changes for the better, death rapidly follows. Successive collapses, occurring in other parts of the lung are accompanied by symptoms similar to those enumerated, but their onset is more gradual. Death may result from exhaustion following lung fever, cough and continuous struggle for breath. When recovery takes place the period of convalescence is very prolonged, so much so in fact, that it is difficult to define the stage of resolution.

It is during dentition that bronchopneumonia most frequently occurs. It has also been observed that scrofulous and rickety children are almost apt to contract it.

It can scarcely be confounded with any other disease except croupous pneumonia. To be sure it resembles acute bronchitis in the beginning, but the evidence of grave conditions may not be accounted for by a simple bronchitis. It differs from croupous pneumonia in that the attack often follows previous illness, as whooping cough or measles. The fever rarely reaches 104-105° in the first twenty-four hours of the attack. Dyspnœa more pronounced; accessory respiratory muscles brought into action; patients are usually under three years of age; consolidation of patches of lung on both sides, over which dullness on percussion is not marked; moist subcrepitant rales and occasionally coarse crepitation; its indefinite duration, prolonged convalescence and fatal tendencies.

Physical examinations reveal very little in the beginning, and it is only after the disease has made some considerable progress that we are enabled, by this means, to differentiate it from other forms of lung trouble. Hence we have to rely mainly on rational signs. The respiration, as the bronchioles and parenchyma become implicated, increases in frequency, sometimes numbering 60 to 70 per minute. The pause which ought to follow expiration now precedes it; costal breathing takes the place of abdominal; and retraction of the epigastrium and the intercostal and supraclavicular spaces are further evidence of incomplete expansion of the lungs. The pain which accompanies the respiration may be due to pleuritis, but the moaning sound on expiration may be present when no pleuritis can be found, and then it is not always to be accounted for. Hydrothorax is extremely rare though pleurisy is present in a large percentage of cases, and generally circumscribed. The tongue and mouth, in protracted cases, become dry; sordies collect; thirst is intense; frequently there is vomiting and diarrhœa; stupor in varying degree, is nearly always present—sometimes it is so profound as to simulate coma.

The prognosis should always be guarded, for although the physicial signs show little to cause alarm, consolidation and collapse may come on without warning and speedily render a seemingly mild case a very grave one. In children of one year and under the fatality is greatest, the younger the child the less the chance of recovery.

Has there been previous illness? Especially whooping-cough or measles? What are the powers of resistence in the child? Does it take and retain nourishment? Is there diarrhœa? Does the temperature remain high for a considera-

ble time, and if so, how does it affect the patient? Is the heart's action strong? If not, how is it affected by stimulants? Is there stupor or delirium, and how severe? Is the cough loose, and are the efforts strong enough to force the bronchial secretions above the glottis? These are all pertinent questions concerning which we should satisfy ourselves before making statements or promises which might afterward make us appear at fault.

So far as possible, provide for the comfort of the patient. It should have intelligent nursing; the room should be well lighted and ventilated, and a temperature of 70° F. maintained. Water in an open vessel should be kept constantly on the stove. If this does not moisten the air sufficiently, steam may be produced by dipping hot flat-irons or bricks into water. Poultices on the chest are worse than useless. Apart from the trouble of preparation, they might embarrass respiration and are uncomfortable, hot or cold. I find the best results from using a vest of cotton batting next the skin, covering the entire chest, sides and back. It should fit snugly but not tight. The patient should be bathed frequently without removing the covering.

If opiates are indicated, the camphorated tincture, or the syr. Doveri, combined with solution of acetate of ammonia, will be found the most convenient. For the cough, apomorphia in doses of 1-200th gr., may, if necessary be repeated every half hour until vomiting is produced. These are only adjuvants however, to the remedy in which I place main reliance, which is calcium sulphide. It not only relieves the fever and cough, liquifies the bronchial secretions, prevents diarrhœa and vomiting, but it cuts short the attack and reduces to a minimum the liability of the disease leaving behind it any serious after effects. I find a ten per cent. triturate, in one or two grain doses, the most convenient and efficient. Powders may be placed upon the tongue, either dry or slightly moistened, and repeated often enough to produce and maintain the characteristic odor in breath and gaseous dejections. Diet should be light and nourishing; water freely allowed; brandy or whiskey in water or milk during attack, and to hasten convalescence change the air, etc.

# SOCIETY REPORTS.

[OFFICIAL REPORT.]

### DISCUSSION OF PAPER SURGERY OF TUBAL PREGANCY.

[This paper appears on page 507 of this issue]

DR. KING: Mr. President, I feel very much like doing as I heard of a gentleman once doing, who got tired saying his payers at night. He wrote out a beautiful prayer and pasted it up on the head of the bed, and when he retired, he pointed to it and said, "Lord, those are my sentiments."

I have not had the experience in this subject that would warrant me in discussing this paper and undertaking to advance new ideas upon it or in any way to controvert any of the positions taken by the writer. Dr. Price has certainly had enough experience in this matter to warrant him in taking and holding the position which he says he has proven at the bed side with his apron on. Knowing him, as we do, as a worker and a thinker, we are bound, at least I feel bound, to accept his opinion.

I say I have had no experience in this matter; I mean to say that I have had no experience in operating. Some years ago I saw three cases, in the course of six or seven years, that I diagnosticated, under the then teachings of Emmet and others, asbeing pelvic hæmatocele—three cases in

which there had been sudden rupture with hemorrhage, which was made manifest by the doughy feel through the vagina. In one instance I remember it appeared so low down at the side of the vagina as to make it perceptible to the eye. I then called them hæmatocele, and I have no doubt now in the present advanced knowledge of the matter, they were all three cases of ruptured tubal pregnancy. I presume in those three cases the fetus escaped upward, and, as I wrote to Dr. Price when he got through his speech, that

> "My little cases sat upon the pancreas
> Waiting for Dr. Price to come;
> And to while the weary time away.
> Played upon the light duodenum."

Neither of the women died; they all three got well. How they are doing now, I can't say because I have not had a chance to observe the cases since. I saw two of them in consultation, and one of them in my own practice. One of them finally moved away. I don't know what their condition has been since. I saw another case, which without rupture, I diagnosed as tubal pregnancy; it was seven years ago and, following the advice of Beard and Rockwell in the methods for destroying the fetus with currents of electiricity, I used that. After using it for three or four times there was a decided diminution in the size of the tumor. I felt satisfied that I had destroyed the fetus. Last week I was called to see this same woman in Sedalia, my old home, and I found her in bed with this history: up to a few months ago she had been unusually healthy; she had gained in flesh and had been stronger. I believe she had not missed her menstruation, but had gone to bed recently with a hemorrhage, and upon examination the physician made out what he thought was a fibroid tumor, and what I am satisfied was a nodular fibroid. In the examination I made I found a fibroid which seemed to have bored posteriorly into what was no doubt a retroverted uterus, with one projection of the tumor anteriorly up into the abdominal cavity, some old mass in the region of the left tube and the ovary softening and appearing to be an abscess. The woman had had a rise of temperature. She will come here in the course of two or three weeks, for operative procedure and some of you will perhaps see the case with me and we will see what it is. I think I destroyed the fetus at that time and now there has followed the development of a fibroid tumor. The woman is thirty-eight years old, and bore one child twelve years ago, and this condition you know has favored development of a fibroid. I think she has a very complicated tissue there. I will perhaps remove the tubes and ovaries with this mass, and perhaps do an abdominal hysterectomy.

I want to say in conclusion, that I do not undertake to discuss this paper; my experience doesn't warrant it. I must accept what Dr. Price has said. But I do want to join with the members of this society in thanking Dr. Price, not only for the admiral paper but for the admiral teaching he has done in his visit here.

---

Refined Tastes.—A rather pointed story is told of Senator Blackburn, of Kentucky, and the late Senator Beck, which we give without varnish.

Upon one occasion it was necessary to test some old Bourbon whiskey before shipping the Simon Pure to a fastidious customer. The anxious dealer bethought him of these two great men, who were universally admitted to be connoisseurs in the article, and begged their indulgence in the matter of tasting the liquor. Blackburn swallowed a sip, smacked his lips, looked a little bit critical, tried it again, and then said, "It is fair,—very fair,—but," again smacking his lips, "It seems to me I taste iron in it." The dealer looked discouraged.

Beck went through the same process of tasting and trying, at last exclaiming, "That's good,—very good,—but I think I detect a taste of leather."

The dealers face fell. But, feeling sure he had a superior article, he investigated. After diligent search, he found a *carpet-tack with a leather cap* in the bottom of the cask.—*Harper's Magazine.*

**His Offspring.**

"My pigmy counterpart," the poet wrote
Of his dear child, the darling of his heart;
Then longed to clutch the stupid printer's throat
That set it up—"My pig my counterpart."—*Harper's Weekly.*

# THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A.M., M.D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316-18-20 North Broad Street,
PHILADELPHIA.

**TERMS**:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

**REMITTANCES** should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

**NOTICE TO CONTRIBUTORS**:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, SEPTEMBER 30, 1893.

## EDITORIAL.

### THE DOCTOR AND THE COOK.

It is the popular belief that the relation between the physician and the cook is only that the former profits by the work of the latter. And in truth the cook has been a stay to the physician—an inexhaustible source of work for the medical man.

That medicine has become the science of the prevention of disease rather than the cure of it, is true despite weary iteration. Likewise is it true that the intelligent application of dietetic and hygienic measures is supplanting the empirical use of drugs. More and more is the attention of the medical profession given to removing the predisposing as well as the exciting causes of disease, anticipating rather than awaiting the actual presence of sickness. Greater dependence is placed upon fortifying and reinforcing the citadel threatened than upon trusting to the explosion of some hidden mine to rout the enemy in actual engagement. This tendency of modern medicine is the natural outcome of appropriating the advanced results of collateral sciences and making practical use of them in the interests of diseased humanity.

Medical students are prone to regard the time spent in the study and the laboratory on such subjects as physiology or chemistry, as being out of proportion to the benefit to be derived when the opportunity comes to put to practical application the lessons learned as students.

This objection appears pertinent, and even logical, so long as there obtains that mis-begotten product of ignorance and superstition, the belief that treatment consists principally in the application of drugs, and that diagnosis means the selection of a proper remedy.

That the student mind does not appreciate the great importance and mutual dependence of his preparatory studies, is more the fault of his teachers than of himself. He pursues his various studies as separate and distinct branches of science. He has a vague impression that these different branches bear more or less on the general practice of medicine. Just how he cannot at the time understand, and he is left to his own resources to find out. The average medical student, especially if he has received no training preliminary to his professional education, is not capable

of judiciously selecting and assimilating that which is valuable and necessary from the heterogeneous chunks of information hurled at his devoted head during his attendance upon two or more full courses of lectures in a medical school.

It follows that he gives his attention to what he regards as the most important studies, to the neglect of those whose value is not evident to him, and not until he has graduated and, having survived the inevitable attack of macrocephalus, learned how utterly inefficient has been his preparatory training, does he appreciate the importance of the branches neglected. How could it be otherwise when the great one from his chair of Practice, delivers an oracle concerning some disease—its etiology, pathology, symtomatology, diagnosis, prognosis and treatment—all dogmatically and without an anatomical, physiological or chemical reason or explanation in the whole extract from ancient authorities.

It is no easy matter to specify just what and how medicine should be taught, but, it is evident that there will be a great economy of time and energy when admission to the study of medicine can be gained only by demonstrating a thorough grounding in the elements of the collateral sciences. Surely the medical school is not the place for teaching elementary chemistry or botany or physiology or the like.

When the student comes ready to apply principles already learned, teachers will no longer be able to comfortably give kindergarten shows, but in order to survive will be compelled to strain every nerve to perform their true functions, namely the gathering, sifting, selecting and preparing, from all sources of modern medical thought, pabulum ready for digestion and assimilation by discriminating minds of earnest researchers. This may be an ideal condition, but the steady advancement of the standards of medical education gives much promise for the future.

Under existing conditions, the physician, painfully realizing his lacks and the necessity of unlearning much that he has been taught, seeks information from all available sources and thereby acquires knowledge. This acquired, he endeavors to put it to practical use. Herein is wisdom.

The subject of food and its proper application is now assuming imposing importance. Familiar with the physiological processes of tissue building and waste, the whole subject of nutrition is opened up for study. This brings into play chemical as well as physiological wisdom—that is knowledge applied. But to obtain the desired ends it is not sufficient to know only the general character of the required foods. The physician must know not only what food stuffs will answer the requirements, but he must know how such food stuffs are to be prepared to work efficiently. This carries with it some knowledge of the kitchen for the simple reason that cooking involves processes of chemical change which may make or destroy entirely the value of the food stuffs.

In sooth, the physician is expected to know all of some things and some of all things. The physician knows it is not sufficient to give the very vaguest instructions as to what a patient may or may not eat, and trust to the ordinary kitchen mechanic to produce the desired results. He must, if necessary, be able to give for the preparation of food directions as specific as he gives the pharmacist for the preparation of medicine. This does not necessarily mean that every physician must qualify as a *chef*. It will be sufficient for practical purposes, if every physician will study the food stuffs in common use in the locality in which his work lies, and learn so that he can teach the modes of preparation by which the nutritive values of the various food stuffs may be developed.

The physician in the kitchen is no longer a joke.

# TRANSLATIONS.

## PEPSIN AND THE FERMENT LAB; ESTIMATION OF THE DIGESTIVE POWER OF GASTRIC FLUID; ARTIFICIAL DIGESTION.

Bouveret (*Gaz. Med. de Paris*, June 3, 1893) remarks that the gastric juice contains two ferments to which it owes its digestive activity, pepsin and the ferment lab or the ferment of rennet. The quantity and the quality of these ferments may be modified in pathologic cases, and it is important to recognize these modifications. There are no rigorous methods, however, by which these researches may be made. The pepsin is secreted in the gastric glands, probably by the principal cells, as the substance pepsinogen, the propepsin of Schiff, which as yet does not possess the property of digesting albumin. This property is communicated to it by the acids especially by hydrochloric acid, which appears to be of all the acids the one which separates from pepsinogen the most rapidly and the most completely the active ferment, pepsin. It is rare that propepsin is entirely absent, even in cases of extensive and grave lesions of the stomach, and the variations of the activity of the pathologic gastric fluids depends upon the variations in the acid element. It is generally admitted that a proportion of hydrochloric acid of 2.5 parts to 1000 is that which most favors the action of pepsin upon albumin, in other words, it is that solution of hydrochloric acid which, with a certain quantity of propepsin, appears to separate the greatest quantity of pepsin. Gastric fluids very rich in hydrochloric acid are not always those which digest the best.

Langley has discovered a means of distinguishing the substance pepsinogen from pepsin; the carbonate of soda destroys this ferment while it is without action upon propepsin. In the stomach mucosa of an animal recently killed, pork for example, there are coexistent propepsin and pepsin which must be separated by appropriate solvents; on heating the mucosa with water both of these substances may be extracted, while glycerin will dissolve only the pepsin. In the gastric fluids the presence of pepsin is usually determined and the degree of activity is approximately estimated. Two conditions may exist: 1. The fluid contains free HCl; 2. The fluid does not contain free HCl. Pepsin always accompanies HCl. It may be, however, more or less active, and the simplest way of appreciating this activity consists in submitting the filtered gastric fluid to the test of artificial digestion. For this purpose the same quantity of the gastric juice should be employed, for example, 10 to 20 centimeters. To this is added some albuminoid substance to digest such as the boiled white of egg, fibrin or the albumen of serum. The white of egg is generally preferred, because it is the most readily procured. According to the researches of Jaworski three hours are required to digest, at the temperature of 40° C., a fragment of coagulated white of egg of 5 centigrammes, placed in 25 cubic centimeters of gastric fluid of normal composition. An hour and a half will digest the same weight of fibrin and the dissolution of the albumin of serum is still more rapid. The method of dilution of Brucke permits the comparative estimation of the quantity of pepsin contained in different gastric fluids.

In the second case, *i.e.*, when the gastric fluid does not contain free HCl, the reaction of Gunzburg is negative. This fluid may be neutral. If albumin should be digested by such a fluid it is due to the accidental admixture of some pancreatic juice with the gastric juice, for a *neutral gastric juice that does not contain pancreatic juice will not digest* albumin. An acid gastric juice containing HCl will not digest albumin unless a part of this acid is in a free state. It is very interesting to search for the presence of propepsin in gastric juice deprived of HCl. Complete absence of this propepsin is very rare, but it is a sign of great value, and indicates, if it is constant, an advanced if not a complete destruction of the glands of the gastric mucous membrane.

*Labzymogen and the ferment lab.* We know to-day that the coagulation of milk is due to a special ferment, the ferment of rennet secreted by the glands of the stomach. Recognized by Payen, this fer-

ment has been completely studied by Hammarsten. Since then, it is generally designated under the name of the ferment lab or lab-ferment. As in pepsin, the lab is preceded by a proenzyme, the labzymogen from which it is separated by the acid, especially by hydrochloric acid ; in some way in gastric fluids there is ordinarily a certain parallelism between this acid and the ferment of rennet. Labzymogen resists the action of alkalies, which even in very feeble dose, destroy the lab. The influence of lab upon milk is independent of the acids and of the pepsin. Selmi has shown that the lab suffices to produce a coagulation of milk in the presence of lactic acid and Hammarsten has separated pepsin from the ferment lab. Moreover, these two ferments do not act exactly under the same cenditions ; there is needed an acid medium for pepsin to digest albumin, while, lab, also active in an acid fluid, coagulates milk very well in an entirely neutral medium. It is nevertheless probable that the two ferments are secreted by the same glandular elements. Under the influence of neutralized gastric juice milk coagulates in a few minutes. The coagulum, at first voluminous, retracts little by little, and permits the serum to exude; This retraction takes place slowly, the lab passes out in the serum ; in truth, the serum is capable of coagulating a new quantity of milk. The casein thus precipitated is slightly soluble in acids and weak alkalies. The reaction of the medium is not modified during the phenonenon of coagulation ; the liquid remains neutral. The coagulation of milk by acids does not present the same characteristics. The temperature of 34° to 40° C. is most favorable to the action of lab. At 70° C. the lab is destroyed but not the labzymogen. The determination of lab may be qualitative or quantitative, and two conditions exist, as in the case of pepsin, according as to whether the gastric juice contains free HCl or not. In the former case neutralize exactly 10 cubic cm. of this liquid, and add one equal quantity of fresh or boiled milk preferably the latter (Boas), the mixture taking place at a temperature of 38° C. In ten or fifteen minutes, if lab be present, coagulation is completed.

## THE ETIOLOGY OF THE PRIMARY CARCINOMA OF THE GALL BLADDER.

Dr. F. Siegert, Geneva, (*Virchow's Archiv*, 1893) says : The question, is carcinoma of the gall bladder the cause or the result of the cholelithiasis which is so frequently observed with this disease. This is answered by the clinicians, as a rule, that the changes found in the gall bladder due to the presence of carcinoma, together with the failure of contraction and the abnormal secretion or formation of free bodies, owing to the degeneration of the tumor, all will aid in the production of gall stones.

The proof of this latter view was not generally acknowledged. Clinically the theory was that first cholelithiasis was present and that later the tumor formed in the walls of the gall bladder ; pathologico-anatomically it was the fact that in this or that case the size of the gall stone present was in direct relation to the age or size of the carcinoma.

A third method is described by Siegert; for instance, if the carcinoma is the cause of cholelithiasis, it would become absolutely necessary that gall stones should form with equal rapidity in primary or secondary carcinoma of the gall cyst.

The author has studied the literature of this subject carefully, and has collected a number of cases which have led him to the following result. The primary carcinoma of the gall bladder was found, 15 per cent. in males and 83 per cent. in females (2 were doubtful, since their description in literature was somewhat vague). Of 95 per cent. of gall stones, in 3 per cent. there was no primary carcinoma and in 2 per cent, it was doubtful. On the other hand there were found of secondary growths 77 per cent. in males and 23 per cent. in females; of these there were in from 15 to 16 per cent. gall stones present, and in 84 to 85 per cent. none.

Through these facts we have a certain amount of proof that secondary carcinoma of the gall bladder does not always of a necessity produce cholelithiasis. Should this occur in the secondary form occasionally, it may be just as much due to a possible previous formation of stone.

In primary carcinoma gall stones are found almost without exception while in the secondary form only exceptionally. For this reason the author thinks that the formation of the stones in the primary carcinoma are not the result, but may be the cause of the same (stones were found in cases in which macroscopically a carcinomatous change of the gall bladder could not be proven, reference case 7 of the original.)

The primary carcinoma is found 5 to 6 times more often in women than in men; the cause is supposed to be a mechanical one, namely, tight lacing. The secondary form, however, occurs more frequently in the male, which can be explained by the fact that the primary seat of the carcinoma is more often found in the digestive tract, which is not the case in the female.

## CONTRIBUTIONS TO THE OPERATIVE TREATMENT OF CONGENITAL HIP-JOINT DISLOCATION.

Dr. Hoffa, Wurzburg, (*Munchn. Med. Wehnschr,* 1893) reports the result of cases which he had operated upon and described 3 years ago. The operation consists in the reposition of the dislocated head of the femur into the newly made, or frequently present, acetabulum. The author has, up to date, performed this operation 26 times. His experience has taught him that it should be done early, before the muscles attached to the pelvis and the thigh become contracted, otherwise it may become necessary to relieve these contractions. The theories differ somewhat about the success of this operation in congenital dislocation of the hip. For instance, the supposition that in most cases there is an absence of the acetabulum, is not advocated by the author, since close observation will always disclose a flattened space where the cavity should be. Even if not quite plain one can be readily formed artificially.

In order to perform this operation it becomes necessary to increase the depth of the old cavity, care being taken that the margins of this new formed acetabulum remain sharp. This will favor the normal position of the head of the femur, and is more readily done in the cases of congenital dislocation of the femur, since the region of the acetabulum forms the thickest portion of the entire pelvis. The head and neck of the femur present generally no difficulty after once having been replaced.

The author gives further new instructions about the technique of the operation and then presents the results of his operations. The operation will do away with the limping and lordosis of the one side; if the dislocation is on both sides, the results are equally good.

There is one point to remember in the one sided luxation, and that is, that the operation will not entirely remove the probable shortening of the extremity, since during the time before treatment it has become somewhat diseased.

Without operation in the orthopædic treatment such good results are never obobtained. This is amply shown in the decidedly hypertrophied ligamentures which becomes inclosed between the head of the femur and the pelvis.

---

An Attorney's Speech.—A colored attorney practicing in a court not a thousand miles from Richmond, Va., animadverting strongly upon the testimony of an adverse witness, used the following somewhat remarkable language:

"Gentermens ob de jury, yo dun heard all dat bal-haded conterband dun said. But, gentermens, he didn' tell de trufe. Ef he had er ben swore lak he would er ben swore thirty yeahs ago, ef he had er ben tole that unless'n he told de trufe his ears would er ben cut off smack up ter his hade, he would er told de trufe. But stidder doin' dat he kim heah an frejerdis dis jury gin the prisner at de bah, dat' ignunt, discomposed, and eluded man."—*The Green Bag.*

# ABSTRACTS.

## WHEN CATARACT IS READY FOR OPERATIVE TREATMENT.

Dr. Edward Jackson, of Philadelphia, in a paper read before the Pennsylvania State Medical Society, discusses this subject. He says:—

In former papers read before this Society, I have insisted on the importance of completeness in the early diagnosis of cataract. At a later stage, the important point in diagnosis is to determine when the cataract is ready, and ought to be removed. This determination rests upon the recognition of the so-called maturity of the cataract. This maturity may be considered from two points of view—the condition of the cataract as to the interruption of vision that it causes, which might be termed its *visual maturity*, and, second, its condition with reference its *surgical maturity* to easy and—complete removal.

The amount of interference with vision that cataract causes even when this has reached its maximum for the individual cases, varies greatly. In some cases this interference is not very great, even after many years of continuance of the opacity, and with very little probability of any further increase of interference, however long the patient may live. With this condition too, of slight intereference with vision, the cataract may be surgically mature. In another case the opacity may reduce vision to more perception of light, although the cataract is far from surgical maturity.

The amount of impairment of vision that will justify or demand the extraction of a so-called senile cataract will vary with the circumstances and occupation of the patient and the probable future course of the disease if left to itself. After cataract extraction, vision equal to 1-10th as suggested by Graefe, has been looked upon as a perfect result; a higher standard of vision has been proposed in this connection, as by Schweigger, who suggested 1-6th. We can, in any case of cataract extraction, except that the result of operation will be at least this good, with the possibility of being better. Hence, when vision has fallen this low, and the patient's occupation demands the most perfect vision, so that such an impairment is for purpose of labor, practical blindness, we may regard the visual maturity as warranting a resort to operation.

Visual maturity depends, of course, wholly on the amount of opacity in that portion of the lens in a line with the pupil, either in the nucleus or cortex. Surgical maturity depends rather in the alteration that have occured in the portion of the lens lying in contact with the capsule, quite irrespective of any alteration in the nuclear part of the lens.

The surgically mature lens is in better condition for extraction, first, because the cortical substance is less adherent to the lens capsule, and, second, because the opacity of this cortical substance enables the surgeon to determine when it has been completely removed. The opacity of the nucleus is less important, because in senile cataract this comes out as one mass with no risk of a portion being left behind. It is possible for a clear lens to be surgically mature, as in the case of old persons, where the whole lens has become firm and would come out as nucleus. But such surgical maturity alone would not justify removal.

After the lens has undergone degenerative changes, and reached the period of surgical maturity, these degenerative changes generally continue and in time make the cataract less favorable for removal—it becomes hyper-mature. Hypermature cataract may present some fluid portions, but generally presents some portions that are harder and more brittle than any part of a recently mature cataract, if not actually calcareous. A lens in such condition becomes usually a more noticeable deformity, by reason of the white color that it gives the pupil, and is liable to irritate the adjoing iris, and make an irritable eye, and may give rise to sympathetic irritation of the other eye. It is, therefore, best to remove a cataract as soon as it becomes surgically mature.

From what has been said, it will clearly appear that there are two factors to be considered in determining the time for

cataract operation. First, the interference with vision, which will fix the time that such operation is desirable; and, second the conditions which influence the ease of complete removal, which will determine the time when the operation can be performed with the greatest ease and prospect of success.

So long as a patient preserves vision in one eye, the impairment of vision in the other will have little weight in determining the time of operation, because, even if a perfect visual result could be obtained by operation, the difference in refraction of the two eyes would leave binocular vision still impossible. When, however, the power of vision of the second eye becomes so far impaired as to cause interference with, or complete suspension of the customary occupation, the indication of visual maturity is present.

The question will then arise, Is it necessary or best to wait for the surgical maturity of the more advanced cataract? In former years this was always a very serious question and generally to be decided in the affirmative. Although a long period of comparative or complete blindness was thus entailed, there seemed to be no other way to give the patient a good chance for ultimate relief. The gravity of this period of waiting, the loss of time it entails on persons whose prospect of life is at best comparatively short, the reduction of many from self-support to dependence, and the unfavorable influence exerted on the general health of the individual by a period of idleness and comparative helplessness, have stimulated surgeons to seek for methods by which it might be abridged.

The method of rendering the lens opaque by puncturing with a needle as is done in cataracts for young people, has, from time to time, been tried in senile cataract, but has not been found safe or satisfactory.

An operation for the purpose of hastening surgical maturity that has gained general recognition by the profession is that of Fœrster, who removed a portion of the iris, and by trituration of the cornea, and through it the lens lying in contact with it, immediately after the iridectomy, secured the early surgical maturity of the cataract. The trituration with the iridectomy, however, is itself quite a formidable operation; and its results were extremely uncertain, although possibly it is capable of development into a more reliable operation.

But with the reintroduction of extraction without iridectomy, it has fallen still further into disfavor or neglect.

Dr. Bettman, of Chicago, has however, proposed an operation which he calls direct operation, in which he taps the anterior chamber and introduces a spatula into a direct contact with the lens itself and performs a similar stroking of its surface.

Dr. White, of Richmond, acting on a suggestion of Dr. Pooley of New York has also modified Fœrster's operation by omitting the iridectomy. Simply by tapping the anterior chamber and drawing off the aqueous humor, so that the lens falls in contact with the posterior surface of the cornea, the same effect of artificial ripening of the cataract is produced.

These operations, of which the last is probably the most valuable, furnish the means of securing surgical maturity so soon as a cataract causes sufficient impairment of vision to constitute an indication for its removal. Then, too, the advances made in the operation of extraction, enable us now to extract cataracts before they are surgically mature with great safety. For this purpose, the washing out of the anterior chamber, as the last step of the operation, is a most important advance. One of the best means of doing this, and the one I have employed, is that described by Dr. Lippincott at the meeting of this Society in 1890, at Pittsburg.

The danger of inflammation after the extraction of an immature cataract seems to be through the leaving of portions of lens substance in the anterior chamber. This may be entirely prevented by the washing. There is also the risk of not entirely removing the cortex from within the capsule. This, however, does not endanger the safety of the eye, but merely necessitates the doing of an operation for secondary cataract and detracts from the brilliancy and impressiveness of the immediate result.

From what has been said, therefore, it is evident that we can now with great safety, either by preliminary ripening, or by extraction of a cataract not surgically mature, as may best suit the particular case proceed to the operative treatment of se-

nile cataract, so soon as the visual impairment becomes an indication for operation.

In deciding when the impairment of vision is sufficient to warrant any operation, it should be borne in mind, however, that brilliant as are the results of cataract extraction, the removal of the lens, entails the necessity of wearing cataract glasses, which are often so annoying and unsatisfactory, and present such difficulty to the elderly patient to become accustomed to the distortion of the images they cause, that, as Landolt has said, the patient is often inclined to complain more of his glasses than of his cataract. Hence, aside from the small risks of the operation, the certainty that the patient will experience serious annoyance from the necessity of using his glasses, should make us hesitate about the abstraction of cataract, unless the improvement of vision to be secured by it will be marked and unmistakable.

While it may be best for the patient to prevent a long period of enforced idleness and blindness, at least some slight experience of such a condition will have a beneficial influence in lessening his annoyance at the difficulty of seeing under the the conditions of aphakia.

In the cataract of young people, whether congenital or traumatic, the indication for removal is also the probability of improved vision. Young people commonly have less difficulty in becoming accustomed to cataract glasses, and will, in a short time, become entirely satisfied with them, especially if they have not known distinct vision prior to the removal of the catract. On the other hand, if the opacity of the lens, still permits a considerable amount of vision, the young person possessing the power of accommodation, has an advantage that the cataract glass cannot give, and which should be considered before deciding on the removal of the lens.

In many lenses, however, that present partial cataract, this power of accommodation is much less than in normal eyes of the same age, and, often can only be exercised or is liable to be exercised in such a way as to cause eye strain and consequent disease, and permanent danger to the other tissues of the eye.

Then, in any doubtful case, there is the additional reason for early operation, in that the younger the child, the simpler the process of removal. Up to about the age of 15, we can expect the lens to be removed by absorption, after one or more needlings, a slower, but safer and simpler operation than extraction, which will probably be necessary at a later date.

In the case of capsular or secondary cataract, the surgical indication, as well as the visual, is for the earliest possible operation. Such membranes always tend to become more tough and resisting the longer they are left, so that as soon as the condition of the eye warrants operative interference, and it is clear that secondary cataract or thickening of the lens capsule will have to be dealt with, the operation should be performed. Those cases are rather to be regarded as fortunate in which such an operation is done to secure the best visual acuteness within the first few weeks after cataract extraction.

With reference to all forms of operative treatment of cataract, the most serious contra-indication to operation, is any impairment of the general health that is likely to prevent or delay normal healing. In looking back over my own experience, I cannot recall any case of an eye lost or vision damaged after cataract operation, in which there was not some unfavorable condition of the patient's general nutrition. This point has perhaps, too often been lost sight of in this era of improved surgical methods, but it is certainly one of the very greatest importance. As a preliminary to any operation, the patient should be brought into the best possible condition of general physical health.

But it must not, in any case be supposed that even serious organic disease will necessarily lead to an unfavorable result, or that in the presence of such disease, it is not justifiable to take considerable risks for the sake of giving the patient sight during what life may remain. Perfectly satisfactory healing occurs in advanced diabetes, or Bright's disease, or in the presence of such a serious local disease as chronic catarrhal conjunctivitis.

Summary. In conclusion, the points to which I wish to direct attention, are

First.—That in considering the question of operation on senile cataract, we must recognize visual maturity and surgical maturity as distinct conditions.

Second.—That it is sometimes best to have surgical maturity before proceeding to the extraction of cataract, but

Third.—Surgical maturity may be obtained by preliminary operation whenever it is desirable.

Fourth.—The time for extraction will then be determined rather by the visual maturity; not, generally of the cataract to be extracted, but of the cataract in the eye that retains the better vision.

Fifth.—That if necessary, for visual and personal reasons, it is proper to extract a cataract surgically immature.

Sixth.—In young people where some visual power remains, the value of the power of accomodation must be considered in determining the question of operation.

Seventh.—If in young persons, the removal of the lens is deemed advisable, it should be done as early as possible.

Eighth.—In all cases, the condition of the patient's general health should be carefully considered, and given the greatest weight in determining the time for a cataract operation.

## A CASE OF CHRONIC GLANDERS TERMINATING FATALLY IN AN ACUTE EXACERBATION.

The authors of this paper, Dr. Hallopeau and Jeanselme (*Annal de Dermatal et de Syph.*), 1893, gives at the outset a cursory review of glanders occurring in man.

Elliotson and Rayer were the first to establish direct infection. Alibert was apparently ignorant of its occurence in man; English, American and German dermatologists allude to its manifestations, but with few exceptions have had no personal experience with the disease. The pathological and clinical aspects hitherto have been only lightly touched upon, and therefore the authors have given a full clinical, pathological and bacteriological account of the disease.

The patient, æt. 30, a carter, was admitted to the Saint Louis Hospital in April, 1890, and gave the following history:—He had been a carter for the last six years. Some few months after having followed this occupation, one of his horses was taken ill, evidently with glanders, and in the course of three months had to be killed. It was then that the patient first complained of his symptoms. He suffered from general malaïse, headache, periodic febrile attacks, pains in the joints, which were neither swollen nor red, and abundant nasal secretion. He was admitted to the hospital at Chalons-sur-Saône, and there he had several abscesses in various regions of the body; some of these healed spontaneously, others in spite of various applications remained open, discharging viscid yellow fluid. Not getting any better after being a year in the hospital, he came to Paris and was admitted to the Saint Louis Hospital. Again various applications were tried (carbolic acid, boric acid, tincture of iodine, iodoform, aromatic spirits), but without result. Finally, under an anæsthetic, the thermo-cautery was vigorously applied, and in the course of a fortnight the patient left considering himself cured. In fact he was able to work for the next three years without any fresh manifestation of glanders. In 1889 dwellings again broke out, unconnected with the scars of the former abscesses, pan in April he again came to Saint Louis Hospital.

*Status presens.*—He complained of headache, pains in the ears and slight deafness. There was ulceration of the calate immediately behind the median insisors. He denied having ever had syphilis, but he was placed on an iodo-mercurial course, and mouth-washes of perchloride and chlorate of potassium were used alternately. No improvement followed; at the end of six weeks the ulceration implicated the gums and upper lip, and anti-syphilitic treatment was stopped.

The labial and gingival ulceration healed, but a sinus persisted in the palate. During the next six months chronic inflammation of the right lachrymal sac supervened, and in October an abcess, the size of an egg, developed in the right flank, opening and healing spontaneously within three weeks.

The upper lip again became swollen and ulcerated, secreting a gummy yellowish fluid. The contiguous gum was spongy, pus exuded at the necks of the incisor teeth, which became loose and discolored. The palatal ulceration exten-

ded as far as the velum palati. There was an ulcer at the neck of the uvula. The remainder of the buccal and pharyngeal mucosa was unaffected. The larynx was sound, and the voice, as in the past, was quite clear. The nasal fossæ were profoundly altered. The secretion was very abundant, yellowish, viscid, and streaked with blood; there was no ozæna. On examination the floor was swollen, and showed distinct ulceration, especially the mucosa of the right nostril, and a sinus led down to bare bone. The septum nasale was perforated, permitting the passage of a probe from one nostril into the other.

Mercurial treatment was again carried out, but in spite of prophylaxis, it aggravated the buccal and nasal ulcerations, and was consequently stopped. The thermo-cautery was now used with excellent effect: unfortunately, owing to the exquisite pain that persisted for some days, the labial ulcers could not be cauterized as effectually as the others. The general characters of the ulcerative process were as follows :

The ulcers presented a punched-out aspect. The margin was sinuous in some places, dentate in others, but everywhere undermined. The surface was anfractuous, granular, covered with a yellowish viscid secretion through which yellow spots like pustules cropped out. The base was not indurated, and the surrounding area, although swollen, did not present the fibrous thickening of an epitheliomatous ulcer.

In December, 1889, a swelling of the size of a nut appeared in the right canine fossa; this was opened by the cautery, which gave vent to a yellowish viscid secretion The patient suffered greatly from insomnia and sharp shooting pains in the head. During the following five months his condition deteriorated, the right side of his face was inflamed and showed scattered pustules of the size of a hemp-seed. The nostrils were plugged with fœtid crusts; the palpebral conjunctivæ were bathed with a sero-purulent discharge; the ocular conjunctivæ remained unaffected; and the right eye was much the worse of the two. The ulceration of the upper lip had destroyed this completely, laying bare the gum, and in April, 1890, the lower lip was attacked.

Marasmus now set in; constant hectic, uncontrollable diarrhœa, fœtid dejecta, slight jaundice, and albuminuria. Ascites supervened, and the patient sank May 21, 1890.

Three periods may be noted in the above case of glanders.

1. The increased nasal secretion and multiple abscess formation running a peculiar course. This period ended in freedom from any symptom for three years.

2. A second series of abscesses, accompanied by ulceration of the nasal fossæ, hard palate and lips.

3. An acute exacerbation of glanders with exitus lethalis. The diagnosis was surrounded with difficulties, and it was only after the signal failure of mercurial treatment on the two occasions, the absence of any signs of tuberculosis and of tubercle bacilli in the secretions, and careful consideration of the patient's history and occupation, that suspicion was aroused of its being a case of equinia.

Drs. Hallopeau and Jeanselme, by cultures and inoculation experiments on guinea-pigs and on an ass, proved conclusively that their patient was suffering from glanders.

The organisms are short rectilinear or slightly curved rods, thinner at their ends than in the middle, thicker than but not quite so long as tubercle bacilli. The equinia bacilli were never found in masses, but either solitary or in groups of two in the neighborhood of aggregations of leucocytes.

As regards the cultures, these when sown on potato presented an amber color on the fourth day, becoming reddish-brown later on. In bouillon fine spiral filaments appeared the following day after insemination.

In the experiments on guinea-pigs, all of which succumbed to equinia, it was found that in males, when the peritoneum was injected with the virus, suppuration of the tunica vaginalis testis invariably followed, which was not always the case when the skin was the site of inoculation.

The ass showed signs of equinia after being inoculated with cultures derived from potato-media.

The authors draw the following conclusions from their study of the above case:—

1. Chronic glanders may last as long as six years, and this is not exceptional.

2. The disease may remain quiescent and, contrary to Tardieu's observation, as long as three years.

3. Glanders should be suspected after a series of multiple abscesses—subcutaneous or intra-muscular—and in the presence of ulceration of the nasal fossæ, of the buccal mucosa, of the velum palati, and painful swelling of the lacrymal sacs with purulent discharge from the nostrils.

4. The swellings—farcy buds—may discharge and heal spontaneously: the latter is rare. Sinuses that persist would seem to preserve indefinitely the property of transmitting equinia—at least inoculation experiments prove this.

5. The specific ulceration has a predilection for the buccal and nasal mucosæ: in the above case it attacked the lips—the first on record.

6. These ulcers resulted from the breaking down of gummy swellings; they were not consecutive to abscesses, as Tardie had stated, and no suppuration occurred in the tissues of the lips.

7. They differed from syphilitic ulcers, in presenting irregular undermined margins, anfractuous bases studded with yellowish prominences, abundant viscid secretion—farcy oil—and in their resistance to anti-syphilitic treatment. Their course is phagedenic in nature, and hideous deformity often results.

8. The acute fatal exacerbation may start from the nasal fossæ spreading along the nasal ducts, analogous to severe erysipelas.

9. From erysipelas glanders differs in the absence of glandular enlargement, and in the presence of profound destruction of tissues accompanied by formation of pustules.

10. The acute attack may last as long as forty days.

11. The secretions of the labial and nasal ulcers, and especially that of the conjunctiva, are exceedingly virulent. The urine of the patient during the acute exacerbation of equinia gave negative results on inoculation.

12. In all the secretions—both of the patient and of the animals—the specific glanders bacillus was present, either alone or with other micro-organisms (staphylococci).

13. To facilitate diagnosis, cultivations should be made on potatoes, which assume in a few days a reddish-brown color. Peritoneal inoculations in male guinea-pigs are followed in forty-eight hours by characteristic suppuration of the tunica vaginalis testis.

14. The only efficacious treatment is cauterization with Paquelin's cautery, systematically and thoroughly carried out. —*The British Jour. Dermatology.*

---

The Servant was Horrified.—Dr. S. had last winter a newly-arrived Hibernian for a servant; he had also recently purceased a pair of porpoise-leather boots. His wife, attracted by the novelty of the new foot-wear, asked the doctor in the presence of the servant what they were made of, to which he responded "Porpoise-hide."

Shortly after the lady from the Emerald Isle interviewed Mrs. S., and announced her intention of "laving whin me week is up." Mrs. S., somewhat surprised, asked the disturbed domestic the reason for her announced departure, to which Bridget responded, with a horrified air,—

"Yer husband is a docther, mum, an' I've heard them docthers do be cuttin' up people, an' didn't I hear um, wid me own ears, say that the boots of him were made of pauper's hide? It's me own ould father that died in the poor-house, an' I wouldn't be sarvin' a haythen that uses the skin of the poor to cover his dirthy feet wid."—*Boston Commercial Bulletin.*

Unprejudiced Advice.—A Western Senator tells a story of a man travelling in a parlor-car between Omaha and Denver who fell asleep and, as *Punch* would say, "snored profusely from the nose," so that everyone in the coach was seriously annoyed. Presently, says the St. Paul *Dispatch*, an old gentleman approached the sleeper, and, shaking him, brought him out of his slumber with a start,

"What's the matter?" he exclaimed.

"Why, your snoring is annoying every one in the car," said the old gentleman, kindly.

"How do you know I'm snoring?"

"Why, we can't help but hear it."

"Well, don't believe all you hear," replied the stranger, and went to sleep again—*Lippincotts.*

# CURRENT LITERATURE REVIEWED.

THE ANNALS OF OPHTHALMOLOGY AND OTOLOGY

for July commences with a paper by Edward Jackson, M. D., on

**Method in the use of Test Lenses,**

the principal merit of which is that the writer emphasizes the necessity of adopting "method" in determining the refraction of the eye, especially in the use of the test lenses. His "own plan is, after ophthalmocopic examination, which gives an approximation to the refraction, to employ the ophthalmometer, and then the shadow test. In this way the correcting lens is determined, usually within a limit of 0.500 of inaccuracy. The trial with test-lenses is then begun by placing this approximate correction before the eye, finding what vision it gives, and then endeavoring to improve it."

This plan is excellent in theory, but it may be remarked, that the reverse order is often times adopted by other observers, unless opportunity is given for testing with lenses at a subsequent sitting, for not unfrequently the ophthalmoscopic, the ophthalmometric, and skiascopic examinations are in themselves so dazzling and exhausting to the patient, as to unfit him for a subsequent examination with lenses without considerable rest. Specialists as a rule are enthusiasts and when absorbed and interested in "a case" they are too often liable to forget the fact that the patient is becoming fatigued by a prolonged examination. Most patients are somewhat "nervous" when they come to the oculist for the first time to have their eyes examined, and what is familiar to him is altogether new and strange to them; so that a first examination has to be conducted with considerable tact, in order that the patient may feel himself at his ease, and not be vearied by the ordeal.

Dr. Jackson recommends that the "changes in the strength of the lenses should be made by the alternate placing and removing of a supplementary lens in front of the one already selected. These changes should always be sufficiently great to decidedly affect the distinctness of vision, being in different cases and different stages of the test proportioned to the acuteness of vision obtained, and to the patient's powers of accurate observations. The principle of reversal of cylindical lenses should be applied by alternately trying supplementary lenses of opposite kind, or turning the axis first in one, then in the opposite direction. It is essential from time to time to check the answer of the patient, as to his impressions, by requiring him to read aloud the letters on the test card."

This article is followed by one on

**The Pernicious Influence of Albinism upon the Eye,**

by George M. Gould, M. D., who has some very positive opinions about albinism. Whilst admitting that there is a mystery surrounding its etiology, and the curious fact that perhaps only one or two members of a large family born of perfectly healthy parents, will be affected with albinism; he is very positive in asserting that the deficiency and dazzling of vision is principally dependant upon the lack of pigment in the iris, and that the symptoms usually found to accompany it are really the consequences of that same condition, and he cites several cases in support of this opinion. He says: "the pathological significance of albinism, lies, I believe, solely in the fact that the iris or diaphragm of the ocular camera is transparent, or so nearly so that it does not act as a true photographic or physiological diaphragm. From non-opacity or non-pigmentation of the iris follows the entire train of evil results that afflicts the albino, and from this slight cause alone. The combination photophobia, nystagmus, ametropia (often also insufficiency or strabismus), and amblyopia presents a union of four frightful ocular defects that leaves little to add of worse, but I wish to emphasize again my conviction that, each and several, these four things are directly or indirectly due to the etiological factor, a non-pigmented iris. A non-pigmented choroid and lid may exaggerate the evil."

Dr. Gould finds that proper correction of the ametropia lessens eye-strain, lessens photophobia, and increases the power of near range vision and he is hopeful that by employing London smoke coquilles having a round segment of say five-eights of an inch in diameter exsected therefrom directly in the line of the visual axes, and into the openings inserting transparent lenses with the patients' ametropic correction, the peripheral portions of the retina will be shaded, the image fixed accurately at the macula and the nystagmus prevented, with the nesessarily resultant cure of the amblyopia.

A paper by Dr. Howard F. Hansell, on

**Functional Exotropia,**

adds fresh evidence as to the futility of tenotomy of the external recti in cases of functional exotropia with loss of converging power; and the advancement of the interni has also in his hands proved unsuccessful. He considers "the most satisfactory results are obtained from a combination of tenotomy of the externi with advancement of the interni, with the object of securing, immediately after the operation, and retaining for a considerable time, decided convergent squint."

An article on

**The Toxic Amblyopias, their Symptoms, Varities, Pathology and Treatment,**

by Casey A. Wood, C. M., M. D., is a continuation of a previous contribution in Vol 1. It deals especially with Tobacco, Alcohol, and Alcohol-Tobacco Amblopias, and givesa resume of the opinion of recent authors, as well as the results of Dr. Wood's own experience upon the subject. This paper concludes thus:

"When all the symptoms of central amblyopia, due to intoxicants are considered, it ought to be, and as a matter of fact is, easy to detect and differentiate these forms of ocular disease. Uhthoff, thus summarizes the points of *diagnosis between the retro-bulbar neuritis of tobacco and alcohol and that due to other causes* as syphilis, disorders of menstruation, "cold," diabetes, etc. 1. The central scotomata are almost invariably confined to red and green; it is rare to find even blue affected, and almost never yellow and white. 2. The scotomata and visual disturbances are bilateral. 3. Vision does not fall below $\frac{6}{200}$. 4. The form of the scotoma is that of an oval which usually includes and stretches from the fixation point to the blind spot and ties above the horizontal meridian. 5. The vision becomes *gradually* less. 6. The disease affects almost always men. 7. Of more than 40 years of age. 8. *Plain is noticed on extreme ocular movements in the essential retro-bulbar neuritis of women, but is invariably absent in the toxic from.*"

Dr. S. Lewis Ziegler, has a paper on

**A Convenient Prism Scale.**

After giving to Maddox the credit of first suggesting a "Prism Scale," and also referring to Prentice's Prismometric Scale," he describes his own "Prism Scale" which possesses both a horizontal scale in black, and a vertical scale in red. The prism unit is adjusted for a deviation of two centimeters at a distance of two meters, and the two scales are so joined that the angle of a resultant prism can be easily ascertained. The article, which is well illustrated, concludes with a convenient "Table of equivalent prisms with their resultants" and also a "Table of resultant prisms and their equivalents."

Dr. Black, of Denver, in a paper entitled

**Operations upon the Eye for Cosmetic Effect,**

makes a stirring appeal to oculists not to postpone operations on the eye, which are purely of a cosmetic character. A divergent squint should not remain uncorrected or a cataract unremoved, because of hopelessness in restoring vision in an eye. A partial or complete leucoma of the cornea should be tatooed to improve the appearance of the eye, and a pterygium should be removed as early as possible, before serious and irreparable danger has resulted to the cornea.

---

THE VIRGINIA MEDICAL MONTHLY for September.

Dr. James Kerr presents the report of some of

**The Surgical Work at the New Emergency Hospital**

of Washington, D. C., during the past year.

In the treatment of wounds it may be said in general that in the emergency room it is antiseptic while in the operating room it is aseptic. In all cases, not already septic, the operations are conducted aseptically, except as far as the skin itself is concerned. Heat is used for sterilizing everything that goes into or near the wound, except the skin of the patient and the operator's hands, which are prepared by scrubbing, alcoholic, carbolic, and sublimate dressings. The precaution is also added of a permanganate and oxalic acid bath for the operator's hands. Sponges are not used, but, in place of them, mops of gauze or cotton. Hæmostasis is accomplished as far as possible by sponge pressure. Before closing a wound it is flushed with a sterilized salt solution. Silk and silkworm gut are used for sutures. In amputation wounds the author states that he has had no occasion to use any form of drain whatever.

The general management of head injuries comprises carrying out exactingly absolute quietude in a darkened remote corner of the ward, with as noiseless surroundings as possible. Purgation and special attention to the condition of the bowels, warmth to the surface and cold to the head, keeping the patient, in all cases where the unconsciousness has been at all deep, several weeks under this treatment. The practice is to elevate in every case of depression with or without symptoms of compression, and explore in all severe head injuries where fracture is suspected. By exploring is meant reflecting the scalp at the site of injury. The author prefers the chisel to the trephine in operations on the skull. In nearly every case the bone was replaced. In one case of septic meningitis the replaced bone was removed and the process arrested by flushing, packing with iodoform gauze and subsequent drainage. Marked improvement speedily followed and the patient recovered. The author earnestly commends the procedure under similar circumstances, and would, from this experience, support the proposition to do a craniectomy in cases of meningitis other than traumatic. He believes that the rapid course and terrible mortality of intracranial inflammations is largely attributable to the unyielding character of the brain case, in relation to the important and delicate organ it contains; and while the cavities of the meninges cannot be treated wholly as the peritoneum can, if we can locate the focus of septic invasion, and as promptly relieve tension, give exit to inflammatory exudate, pack and drain with gauze, we can probably get the same satisfactory results as follow these procedures in the peritoneum and other serous cavities.

In one case of intra- and extra-peritoneal rupture of the bladder, associated with fracture of the pelvis and extravasation of urine into and behind the peritoneum, laparotomy was performed, the bladder stitched laterally to the front of the pelvis to wall off the ruptured part (as the rent itself could not be reached), and the wound treated by the open method by packing the pelvis behind the bladder with iodoform gauze, and draining the bladder and the prevesical space. The patient was threatened with peritonitis following the operation but recovered.

Dr. George Corrie contributes a paper on

**Ammonii Chloridum as a Remedy in Cystitis.**

The following are some of the conditions in which the drug has been given faithful trial,

with most satisfactory results in every instance:

Cystitis dependent upon stone in the bladder; stricture; hypertrophy of the prostate; deposits of urates, etc.; gonorrhœa (male and female).

Cystic irritation from uterine disease or menstrual disorders; malarial effects; masturbation; early pregnancy; simple urethritis (traumatic) in newly-married women.

Cystic and renal sequelæ of la grippe.

In the majority of instances the urine was rapidly cleared of bladder mucus, blood corpuscles, pus corpuscles, etc., the distressing symptoms disappeared, and in no case did the salt solution occasion any gastric or other disturbance. The salt is given in capsules, three or four times in the twenty-four hours, preferably when the stomach is somewhat empty, each dose to be followed immediately by half a goblet or a goblet of cold water. The capsules should be filled shortly before being used as the salt dissolves the gelatine. No explanation of the mode of action of the remedy is given.

Dr. W. K. Gatewood in a paper on "The Modern Treatment of Sprained Ankle" reports a case rapidly cured by the use of continuous applications of hot water and hot fomentations followed by strapping with adhesive plaster.

Other papers in this month's issue are: "Treatment of Appendicitis" by Dr. John W. Dillard; "Practical Observations on the Formulas and Action of Certain Diuretics and Purgatives in the Treatment of Some Forms of Dropsy," by Dr. Joseph Jones; "Injuries to the Eye," by Dr. R. H. Chilton; "Mistakes in Diagnosis," by Dr. R. L. Payne; and "Notes on Sixteen Cases of Atypical (Mountain) Typhoid Fever," by Dr. John F. Woodward.

## MEDICINE.

### Limited Importance of Albuminuria in the Diagnosis of Bright's Disease.

In a recent address delivered before the Academy of Medicine of Paris, Dieulafoy tried to prove that too much importance is given to albuminuria in establishing a diagnosis of Bright's disease and gauging its gravity, basing his opinion upon observation in sixty cases taken from his hospital wards, and duly classified.

In the first category were included six cases in which death followed all the major signs of uræmia, after having presented most of the minor signs; no albumen, however, had been found at any time, although the post-mortem examination demonstrated the existence of characteristic lesions of Bright's disease.

In a second group he placed certain cases in which albumen was found at certain periods only, outside of which periods it was impossible to diagnose chronic nephritis by searching only for the pathognomonic symptom, albuminuria. Dieulafoy therefore concluded that this symptom had but little value in the diagnosis of Bright's disease. It should only serve to confirm the presence of the disease as corroborative evidence; for being far from trustworthy, it might otherwise lead to a diagnosis of Bright's disease in subjects having had albumen a long time without showing signs of ill health. To avoid having recourse to a symptom proven to be so untrustworthy, this illustrious observer proposes that one should make use of those "minor signs," for the most part unperceived generally, which he was the first to describe under that name in his works on the subject. These minor signs, according to him, serve to indicate the initiatory stage of Bright's disease, the malady itself being characterized by the major signs, such as dyspnœa, cephalalgia, convulsions. He describes, in turn, the symptoms furnished by the sense of hearing, —the buzzing and whistling varieties of tinnitus so frequent in cases of Bright's disease; the strange sign that he designates as the "doigt mort" (dead finger), characterized by a sensation analogous to that produced by putting one's fingers into snow; itching, etc., etc. He also speaks of cryæsthesia, that sensation of feeling cold peculiar to victims of Bright's disease; slight epistaxis in the morning, and also the painful cramps in the legs which only cease on the patient's getting out of bed, are also symptoms to be noted.

Dieulafoy has always found these minor signs of use in the diagnosis of chronic nephritis, and had them controled by measuring the degree of toxicity of the urine of patients; he always found a smaller degree of toxicity than is normal, this serving to prove that the substances to be eliminated by the kidneys remained in the system to gradually poison it.

As to treatment, Dieulafoy considers that milk diet is the only effective means at our disposal. He does not attach much importance to the variations in the quantity of albumen excreted while under the influence of this treatment, as the improvement—the cure, even, of certain patients—is shown by the disappearance of the minor signs, sometimes even by that of the major symptoms. This he has witnessed in two groups of patients where the two pathological conditions were associated,—Bright's disease and chlorosis on the one side, and Bright's disease and syphilis on the other.

He also examined into the matter in which Bright's disease is modified by being associated with gout, chlorosis, or kindred affections. Gout shows itself in the kidneys either by calculi or by nephritis. The kidneys of a gouty subject should therefore be well looked to, as nephritis of an arterial nature is apt to supervene. As to the prognosis, a distinction must be established, in a gouty subject, between the minor signs of Brightism and

albuminuria appearing by itself; in the latter case, it is simply a case of gouty albuminuric diabetes, without much gravity.—*Univ. Med. Jour.*

### Cerebro-Spinal Meningitis.

F. Klemperer (*Berl. klin. Woch.*) reports three cases of this form of meningitis. Case 1. Woman, aged 18, both of whose parents had died of phthisis, had been ill for three or four days with pain in the head and giddiness. On admission there was stupor, restlessness, and great irregularity of the pulse. The abdomen was indrawn, the neck stiff, and the head slightly retracted. The next day there was vomiting, cutis anserina, and *tache cerebrale*. Two days later the stupor was marked, the pupils retracted sluggishly, and labial herpes was present. The pneumococcus was cultivated from the herpetic vesicles, but its virulence was shown experimentally to be slight. The next day the meningeal symptoms were more marked, and there was epistaxis. From this time the patient began to improve, and was discharged completely well about a month after admission. Case 2. Woman, aged 29, began to ail four weeks before admission with pain in the joints. and, later, in the right side of the chest, Exploratory puncture here yielded clear fluid. On February 24th there was some stupor, headache, pain and stiffness in the neck, and a rise of temperature. February 25th. There was vomiting, restlessness, and tremulous movements in the face muscles. On February 27th the pulse was irregular and herpes appeared. Next day there was Cheyne-Stokes breathing. The fundus oculi, as in the preceding case, was healthy. Later the left pupil was less than the right, both reacting sluggishly. From March 10th there was slow improvement, ending in complete recovery. Case 3. A girl, aged 16, whose father had died of phthisis, became suddenly ill three days previously with fever, vomiting, and pain in the back. On admission she was apparently unconscious and very restless. There was great rigidity of the neck, clonic spasm in the left arm, and later, weakness in the right side. On the sixth day, herpes appeared, from which diplococci were obtained. She died on the eighth day, and pneumococci were cultivated from the meningeal exudation. There was no tubercle anywhere. In all three cases many things appeared in favor of meningeal tuberculosis. The author discusses the relation of labial herpes to herpes zoster, and he says that the identity is not yet established. He has investigated bacteriologically the fluid from fourteen recent and five older cases of labial herpes. He thinks that this herpes represents a special localization of the original disease, or that when it is the expression of a mixed or secondary infection it seems as though an ordinary and non-specific cause acts as the etiological or complicating factor. The author thinks that labial herpes justifies the diagnosis of a non-specific or so-called epidemic meningitis as against the tuberculous form. He admits that there is much that is hypothetical in this idea, and that a single case of tuberculous meningitis with herpes would overthrow it, provided that a mixed infection was rigidly excluded. Herpes may accompany the suppurative meningitis of the tuberculous, but not pure meningeal tuberculosis. Recovery is more probable if the meningitis be of the simple kind and not tuberculous.—*Br. Med. Jour.*

### The Staphylococcus in Osteomyelitis.

Bommers (*Deut. med. Woch.*) June 8th, 1893), has succeeded in cultivating the staphylococcus albus from the blood obtained with the usual precautions from the finger in a very acute case. Both bouillon and glycerine agar tubes showed abundant growth, and pure cultures were obtained. It is remarkable that in a case of the most acute osteomyelitis (acute necrosis) the experimentally but slightly virulent S. pyogenes albus should be present.

## SURGERY.

### Frequency of Sequestra in Tuberculosis of Large Joints; Treatment of Joint-Tuberculosis.

Riedel, of Jena, has written on the frequency of sequestra in tuberculosis of the large joints, with observations on the treatment of joint-tuberculosis. Tubercular foci in bones, when no sequestra are present, often heal spontaneously; but the presence of a sequestrum renders healing impossible, unless the sequestrum be removed; hence statistics throwing light on the frequency of sequestra are of the utmost importance. Riedel reports 314 cases of tuberculosis of the six large joints, in which the disease began in the capsule in 32 per cent. and in the bones in 68 per cent.; 67 per cent. of the latter presented sequestra, and in 33 per cent. sequestra were present. Hence, out of 314 cases 45.55 per cent. were devoid of sequestra. If to the above 34 cases of tubercular foci near the large joints are added, the total number is raised to 348, of which 48 per cent. had sequestra. As regards individual joints, in 88 cases of coxitis, 70 per cent. had sequestra; in 116 cases of tuberculosis of the knee-joint, 37 per cent.; in 39 cases of tuberculosis of the ankle, 38 per cent.; in 10 cases in which the shoulder-joint was affected, 50 per cent.; in 48 cases of disease of the elbow, 31 per cent.; in 13 cases of disease of the wrist, 15 per cent.

The tubercular process began more frequently in the bone than in the capsule, as is markedly shown in the hip-joint (84 per cent.). An interesting point relates to the frequency with which the disease begins in the different bones of a given joint. In the hip, for instance, the author determined that in 66 cases with sequestra the primary focus was in the acetabulum in 70 per cent., in the head and neck in 20 per cent., and in the head and acetabulum in 6 per cent., leaving 4 per cent. undetermined.

According to the foregoing figures, the best chances of recovery without operative treatment exist in tuberculosis of the elbow, followed by the knee, and then the ankle. The hip-joint, which is most often treated by conservative methods, offers the least chance of success; so that very few cases are permanently cured by injections, etc. In spite of these statistics, however, the operative treatment of the other joints gives such good results that Riedel would advise its continuance.

The author prefers to operate through longitudinal incisions, especially where cavities are left. These incisions are tamponed and not sutured. Any cross-incisions which may be necessary are united by catgut. The resulting scars are just as good as if the incisions had been closed, and healing in the depths of the wound takes place with greater rapidity and certainty. He speaks strongly against the tuberculin treatment.

In the following statistics from Achen only those cases are designated as cured which were discharged without fistulæ. The total number was 137. Of these 75 per cent. were cured; in 13 per cent. fistulæ remained; subsequent amputations were made in 3½ per cent., and 8½ per cent. died. In 49 resections of the hip-joint there resulted 62 per cent. of cures. Owing to the resulting shortening, the author would be glad to discard resection of the hip; but, seeing that injections of iodoform are particularly useless in this joint, there remains nothing else. He has succeeded, however, in several cases, in removing the capsule and leaving the head of the bone in place. This is best done by means of a transverse incision. After 40 years of age, and even earlier, exarticulation is recommended.

In 51 cases of resection of the knee with extirpation of the capsule, 88 per cent. of cures resulted. As with the hip-joint, Riedel regards the fortieth year as the limit of time in which resections should be made.

In 14 resections of the ankle there were 78 per cent. of recoveries. It is best to operate as soon as the diagnosis is made. Riedel prefers Konig's method.

In 16 resections of the shoulder, 12 were cured.

In 4 resections of the wrist, 3 were cured. As in the ankle, an operation should be made as soon as the diagnosis of tuberculosis is established, without reference to the age of the patient.

Riedel recommends iodoform injections in abscesses appearing above Poupart's ligament which result from caries of the vertebræ; also, in hydrops tuberculosis, and in old persons where it is advisable to temporize. He speaks against the employment of injections in younger individuals.

It is best to operate before the fistulæ appear, because infection with puscocci is apt to cause such intimate adhesions between the surrounding tissues and the tubercular disease that it is at times impossible to effectually remove the latter. A reason for operating early in the disease is that delay exposes the patient to the danger of the development of tubercular processes in other portions of the body.

Sahli, of Langenthal (*Corres. f. sch. Aerzte*, March 15, 1893), writes on the use of iodoform injections in tubercular diseases of bones and joints. The best of all preparations is that employed by Tubingen in which sterilized olive-oil is thoroughly impregnated, by prolonged shaking, with 10 per cent. of iodoform; 4 per cent. dissolves and 6 per cent. remains in suspension. The mixture will readily pass through a reasonably small needle, and an ordinary hypodermatic syringe may be used. It is well to partially withdraw the needle and re-insert it, so as to deposit the iodoform in several different foci. There is little doubt that the effectiveness of the treatment lies in the liberation of small quantities of free iodine by the gradual action of the fluids of the body. Sahli, contrary to the advice of Bohny, often injects as much as 2 grammes of iodoform-oil at a time, and has never produced symptoms of intoxication. Pain or inflammation hardly ever follows, and cold compresses, etc., are unnecessary.

During four or five weeks the injections should be made twice a week; and then, for the same length of time, once every one or two weeks. The patient should then be carefully watched for some time. In severe cases the treatment must be continued much longer, and the individual should not be lost sight of for at least six to twelve months. Improvement should begin after four or five injections, but care must be taken not to stop the treatment too soon.

Sahli would recommend the treatment of *all* cases of tubercular disease of bones and joints by iodoform injections, with the exception of those presenting large abscesses, extended destruction of bone, and multiple fistulæ, which are better suited for amputation. If nothing is accomplished, at least no harm will be done. The process is especially adapted to the after-treatment of cases which have been curetted. The elbow- and the hip-joint respond best and most quickly.

Sahli combines with the injections the creasote treatment, local *massage*, extension, etc., where indicated. He lays much stress upon strict asepsis in connection with the iodoform injections.—*Centralblatt fur Chirurgie*, February 18, 1893.

### Operations in the Vertebral Canal.

Urban defines the indications for operations in the vertebral canal as follows: 1st. Vertebral fractures with pressure upon the spinal cord. The operation is not to be undertaken immediately after the injury, but should be postponed until the beginning of consolidatlon, as it would be extremely difficult in the beginning to firmly set together the broken parts. The proper time, varying with circumstances, would be from the fifth to the eight day, if by that time the symptoms are not on the mend; if after the twelfth week there should be no improvement, the operation should undoubtedly be

performed. 2d. New formations in the vertebral canal. 3d. Spondylitis tuberculosa, after the process has remained stationary during at least several months, and no abscesses are suspected. 4th. As an exploration measure in all cases in which symptoms of localized pressure on the spinal cord are shown, after which, according to what is disclosed, the operation may be completed.—*Verhandlungen der Deutschen Gesellshaft fur Chirurgie*, Bd. xxi.

### A New Method of Cuttiug Æsophageal Stricture.

Abbe describes a new method of dividing cicatricial stricture of the œsophagus, which he practiced with very good results on a patient aged 30. After the performance of gastrostomy, a digital examination is made of the lower œsophageal orifice, and a small conical gum-elastic bougie is guided into the canal by the finger. A string of heavy-braided ligature silk is carried from the stomach to the mouth by passing a very small bougie through the œsophageal stricture. In the case reported by the author, the upper end of the string was brought out by the neck through a wound which had been made in an unsuccessful attempt at external division of the stricture. A larger bougie is now passed from the stomach alongside the string, and pressed tightly into the stricture so as to stretch it. The string is now drawn upward by the fingers, passed to the back of the patient's mouth, and the bougie will be felt to advance at once as the string makes its way into the tense stricture. Larger bougies are now passed, and the string is "see-sawed" upwards and downwards. When the largest size has been passed, a rubber tube of corresponding size is drawn through the œsophagus past the point of stricture, its lower end remaining outside the wound in the stomach. A smaller tube is passed into the stomach for nourishment. The patient can thus drink water for refreshing the mouth, and swallow saliva without contaminating the wounded surface, which the tube also serves to keep dilated. The large tube may be removed on the second or third day, and dilating bougies be introduced by the mouth after the fourth day. Finally the gastrostomy wound may be closed, whenever the patient has gained strength, by a plastic operation.—*Medical Record.*

## OBSTETRICS.

### Gonorrhœa and the Puerperium.

Kronig (*Centralbl. f. Gynak.*, No. 8, 1893) has studied the development of gonococci in nine women after labor. The germs are easily found in the lochia. It is certain that in women with vaginal gonorrhœa the disease may extend into the uterus during the puerperium. Gonorrhœal infection of the uterine cavity may also set up fever even when there is no trace of mixed infection, no other germs being present. Gonorrhœal infection in the puerperium is not of direct danger to life, but frequently leads to complications late in the puerperium, the disease progressing from the endometrium to the tubes. Two cases of this kind were recorded. The first, after the usual careful routine treatment, left the hospital on the fourteenth day. Two weeks later she returned. A perimetric exudation was detected to the left of the cervix. The second case was graver. On the fourteenth day the temperature rose to over 103°, the right elbow became painful, and effusion into the extensor tendons of the right hand occurred. During the third week right parametritis set in, the temperature rising to 104°. Then the pain and parametric swelling subsided. The fluid from the tenosynovitis was sero-purulent but free from germs.

### Unconscious Delivery.

Le Blond (*Jour. de Med. de Paris*, July 30th, 1893) related in July a remarkable case before the Medico-legal Society of Paris. A woman, aged 27, who had been seduced and deserted, was seized with slight colicky pain, but continned to work. In the course of the following night she was attacked with still more severe pain. Thinking that an action of the bowels would give relief, she sat upon her chamber utensil; on straining a live child was born. This alarmed her greatly, but she cut the cord with scissors, wrapped the infant in a cloth and walked downstairs, telling the people in the house, in fear and trembling, what had happened. Violent flooding set in. The cord had not been tied. Early in the morning Le Blond saw the patient, and found the placenta still in the vagina. He extracted it. The mother and child did very well. Had the child died the mother would have been very strongly suspected of murder, especially if she had attempted to defæcate in a public privy, in which case the child would almost inevitably have been killed.—*Br. Med. Jour.*

### Fœtal Peritonitis Severing the Intestinal Canal.

Mackenrodt and Keller (*Centralbl. f. Gynak.*, No. 28, 1893) read, at a recent meeting of the Berlin Obstetrical Society, cases of death of infants, one week old, from intestinal obstruction. In Mackenrodt's cases, the infant died at the end of a week, after vomiting fæces for two days. The abdominal cavity showed all the signs of chronic peritonitis, free adhesion of intestine, indurated patches, etc. The peritoneal cavity was full of yellow fæces which had escaped through a larger perforation, with sloughy edges, in the small intestine. A circular band of dense inflammatory deposit completely surrounded and obstructed the small intestine in the middle of its course, and had broken the continuity of the intestine through atrophy. The proximal side of the alimentary canal was greatly dilated. The lumen of the severed distal part was very small, nor could the ileum be distinguished from the colon. The mother had borne five healthy children, and showed no signs of

syphilis. Keller's patient was a male infant; it vomited all its milk in whatever way administered. It died at the beginning of the second week. The appearances were as in Mackenrodt's case, excepting that there was no perforation, and that the closed severed ends of the small intestine were smooth. He believed that the peritonitis was the primary disease in both case. It had hindered the development of the intestine. Olshausen disagreed with this theory, believing that the malformation of the intestine was the cause of the peritonitis.—*Br. Med. Jour.*

## GYNECOLOGY.

### Spontaneons Amputation of an Inverted Uterus.

Hutson (*Archives of Gynæc.*,) relates a case in which the patient was a mulatto aged about 35. She had aborted several times and never carried a child to term. A negro midwife attended her and delivered the child and placenta "naturally," after the custom in South Carolina, the patient being placed in a kneeling position before a chair, whilst uterine contractions were stimulated by shaking her up and down. When the patient got up to go to stool the uterus came down. She lay for three days longer on a filthy mattress in hot weather. Huston was then called in. She was in an unconscious condition, the abdomen being enormously distended, while a putrid pulpy mass protruded from the vagina. It was the inverted uterus which had virtually amputated itself by the contraction of the cervix upon the ligaments and tubes. The sloughy organ was removed and the vagina plugged with gauze smeared with carbolized vaseline. The patient, who at the time seemed to be dying, made a good recovery.

### Conservative Operation on the Ovaries, Tubes and Uterus.

A. Martin (*Deut. Med. Woch.*, 1893) draws attention to the importance of this subject. (1) Resection of the ovary. Ovarian disease is very frequently bilateral, but sometimes circumscribed cystic disease may be found in other ovary. The question arises as to whether the whole organ should then be removed. It certainly should be if there is no healthy ovarian tissue left or the process be a suppurative one, but in some other cases it may not be necessary to remove it. The author refers to 27 such cases with one death; two of these relapsed, and of the 24 remaining ones eight bore children. Ignipuncture has been employed, but the author is satisfied with incision and stitching up. (2) Resection of a stenosed tube, the other being removed for disease. Here it may be more difficult to recognize the character of the disease. The contents of the tube must be most carefully looked to. If the contents be turbid or unmistakably purulent or if the mucous membrane be ulcerated, the tube must be removed; otherwise resection with the formation of a new ostium may be practiced. If any doubt exists, the whole appendage must be taken away. Of 40 cases, with two deaths, only four were not cured or considerably improved. Only one became pregnant, but 12 were unmarried, and the husbands of some others were neurasthenical or had had gonorrhœa. (3) Enucleation of myomata. The older the patients the more likely are myomata to be multiple. In 141 cases of intraparietal myomata, 26 died but this includes the period of development of the *technique* of laparotomy; of the last 20, only one died. Of the 115, only four relapsed (three per cent). The author has not found any difficulty in stitching up the bed of the tumor, nor has any unpleasant hemorrhage occurred. Only two of these patients became pregnant, but other causes of sterility may exist. The author concludes (1) that the conservative operations do not present any materially greater risk than radical ones; (2) that women are thus relieved of their troubles in by far the greater majority of cases; (3) that relapses are exceptional; (4) that the female functions persist; (5) that child-bearing is possible; and (6) that child-birth then takes place without any special risk.—*Br. Med. Jour.*

## NEWS AND MISCELLANY.

### Board of Health Resign.

Four or six members of the Columbus, Georgia, Board of Health including the President, Dr. Ticknor, resigned because the city council refused to pass the ordinance of quarantine against Brunswick.—*Jour. Amer. Med. Ass.*

### The Holy (Cholera) Well at Mecca.

Mr. E. Frankland, writing to the London *Times*, on the condition of the water of the holy well of Zem-Zem, used by the Mahometan pilgrims at Mecca, says: A sample of the water came to me through the India Office. It was full of dead microbes and contained, in an equal volume, considerable more animal matter than is found in average London sewage. In addition, it afforded evidence of previous pollution with an amount of such matter at least six times as great as that contained in an equal volume of average London sewage. The water has been again, quite recently, analyzed by Colonel Bonkowski Bey, consulting chemist to his Majesty the Sultan of Turkey. His results confirm my own analysis. They show that the water is still abominably polutted by excrementitious matters. The surroundings of this well are such as would be likely to impart to the water these dangerous ingredients. Mecca appears to have no sewerage system; all foul matters being buried in the earth within or near the city. Hence the

foulness of the water percolating into the well through this mass of corruption. Colonel Bonkowski Bey informs me that Mecca is supplied with water of excellent quality, but, of course, the pilgrims are bound to drink at the holy well. Tens of thousands of pilgrims continue to die of cholera at Mecca and to spread the disease elsewhere; but, so far as I know, no measures have been taken to prevent pollution, and Mecca continues to be a cholera center.

## ARMY AND NAVY.

U. S. ARMY FROM SEPTEMBER 17, 1893, TO SEPTEMBER 23, 1892.

1st Leiut. Charles F. Kieffer, is relieved from further duty at Fort Meade, S. P., and from temporary duty at Fort Yellowstone, Wyo., and will report to commanding officer at Fort Assinniboine, Montana, for duty.

1st Lieutenant William F. Lewis, Assistant Surgeon, will upon being relieved from duty at Fort Assinniboine, Montana, by Lieut. Kieffer, report to commanding officer Fort Apache, Arizona, for duty.

1st Leiut. Benjamin Brooke, Assistant Surgeon, will proceed at once from Fort Leavenworth, Kansas, to Fort Brady, Michigan for temporary duty duringthe absence on leave of Assistant Surgeon Paul Clendenin, U. S. Army.

Leave of absence for one month, to take effect upon the arrival of Assistant Surgeon Benjamin Brooke, is granted Captain Paul Clendium, Assistant Surgeon U. S. Army.

Captain Curtis E. Price, Assistant Surgeon, relieved from duty at Fort Wadsworth, N. Y. and ordered to report to the commanding officer, Fort Ponter, N. Y. for temporary duty at that post.

Captain Wm. C. Shannon, Assistant Surgeon, is relieved from duty in the office of the Surgeon General of the Army, and as assistant to the attending in Washington, and will proceed to N. Y. City and report in person to the Commanding General Department of the East for duty as attending surgeon and examiner of recruits in that city, relieving Captain Guy S. Edic, Assistant Surgeon.

Captain H. S. T. Harvis, Assistant Surgeon U. S. Army, is relieved from duty at Fort Kiogh, Montana and assigned to duty at Fort Preble, Maine.

Captain M. W. Wood, Assistant Surgeon U. S. Army, is relieved from duty at Fort Preble, Maine, and assigned to duty in Boston, Mass. as attending surgeon and examiner of recruits.

Captain Francis J. Ives, Assistant Surgeon ordered to proceed from Fort Sheridan, Ills. to Chicago, Ills. and report to Captain Louis A. La Garde, Assistant Surgeon, in charge of the medical section of the War Department exhibit World's Columbian Exposition, for temporary duty.

Captain Guy L. Edie, Assistant Surgeon, upon being relieved from duty in N. Y. City, by Captain William C. Shannon, Assistant Surgeon, proceed to Washington D. C. and report in person to the attending surgeon for duty in his office.

Captain Wm. G. Spencer, Assistant Surgeon is granted six (6) months extension to sick leave of absense granted, in Special Orders, No. 108 A. G. O. May, 13, 1893.

Captain Louis Buechemin, Assistant Surgeon, is granted twenty-three days leave, to take effect about September 17, 1893.

Major Aenry McEldervy, Surgeon U. S. Army, is granted leave of absence for one month to take effect about October 1, 1893.

Lieut. Champe C. McCulloch, Jr. Assistant, Surgeon, is relieved from duty at Fort Sam, Houston, Texas, and ordered to Fort Ringgold, Texas, for duty relieving Capt. James E. Pitcher, Assistant Surgeon. Captain Pitcher, upon being relieved, ordered to Fort Niagara, N. Y., for duty relieving Captain Reuben L. Robertson, Assist. Surgeon Capt. Robertson, upon being relieved, ordered to Fort Omaha, Nebraska, for duty.

Leave of absence for one month, to take effect on or about October 1, 1893, is hereby granted Leiutenant Colonel J. V. D. Middleton, Deputy Surgeon General U. S. Army, with permission to apply for an extention of fifteen days.

Captain Lewis A. L. Garde, Assistant Surgeon, will at the completion of his duties in connection with the World's Columbian Exposition, report in person to the commanding general Dept. of the Colorado, Denver, Colorado, for duty as Attending Surgeon and Examiner of recruits in that city.

1st Lieutenant Harry R. Stiles, Assistant Surgeon, is relieved from duty at Fort Omaha, Nebraska, and will report in person to the commanding officer, Fort Meade, South Dakota, for duty at that post.

By direction of the Secretary of War, the leave of absence granted Captain Charles E. Woodruff, Assistant Surgeon, is extended four months.

The leave of absense granted Captain Junius L. Powell, Assistant Surgeon, is extended ten days.

Leave of absence for one month is hereby granted to Major J. Van R. Hoff, Surgeon U. S. Army.

Leave of absence for one month, to take effect about the 5th instant, is granted Col. J. C. Baily, Asst. Surgeon General.

Leave of absence for one month, to take effect between the 25th instant, and the 5th proximo, is granted Major Charles L. Heizmann, Surgeon, Fort Douglas, Utah.

## ORIGINAL ARTICLES.

### "SUGGESTION" IN THE CURE OF DISEASE.*

J. T. AXTELL, M. D., Newton, Kas.

The word "suggestion," as here used, is meant in the same sense as where used by writers on hypnotism, and may be best understood by a history of some cases in practice.

Mrs. D., aged twenty-six; married five years; two children; family history neurotic; was in fair health until three years before this history begins, when, after the loss of a child she became an invalid and went to bed. She complained of pain in her left side just below the ribs and some times extending down into the pelvis, but was not sensitive to pressure. After careful examination no organic disease could be found. She would lie always in one position on her back, with several pillows under her head and the head drawn forward on her chest. Her arms rested on the elbows, with the right hand open and the fingers held straight, while the left hand was open but strongly flexed at the wrist. All the muscles of the body were held rigid, and she would lie in this position for days at a time without moving except when compelled to do so. She did not feed herself nor take any care of her person. The urine dribbled away as it formed and the stools were not always controlled. She was not pleased to be told she was looking well and would never admit that she felt better. Her appetite was good and she was very well nourished. She had many little whims—she could not talk if the door of the room stood open, and, in having her face washed, a certain number of motions must be made in just certain directions,—and she would become very angry if things were not done as she wished. When asked a question it would take her a long time to begin to answer, not because she did not know what answer to make, but apparently because she could not get her muscles to act. When she did speak it was in a very high pitched key and in a jerking manner. She said it hurt her side to talk low, and it hurt her side to take any other position—everything was accounted for by the pain in her side. She did not want to get out of bed and she did not expect to get well. She was sure no one could cure her and she did not seem to care to be cured. There was some loss of mental power, although she seemed quite rational on all points except that she thought she could do nothing and that she suffered a great deal of pain.

I decided to try the effect of "suggestion" alone, and for that purpose took her into my private hospital. At first I hypnotized her every day, and when under that influence her museles would relax and she would get up and walk with a little help. I would say to her, "Now you can walk—your arms are limber now—you can get them above your head—you can hold your head up straight—your side does not hurt you any more. I have taken the pain all away—you can talk easily now."

* Read before Western Association of Obstetricans and Gynecologists, 1892.

When hypnotized she would do just as I suggested and believe just what I told her. After a few weeks it was not necessary to hypnotize her, but I made the same suggestions and she would obey in the same way. She soon learned to walk, to feed herself, to control her urine and her bowels and to take care of her person and of her own room. She stopped complaining of her side, wrote a great many letters, talked quite well and was able to go to her home in Texas.

A similar case was Miss N.; aged thirty-four; family history good; from childhood had not been strong—who complained of a great deal of pain through the chest and about the heart. For many years she was obliged to spend months at a time in bed,and, at the time I saw her, she had been confined to her bed for two years and seven months. She had cramping spells in which the hands would clench anything within reach. The muscles would all become rigid and the head would be drawn down on the breast or, at times, thrown backward. A dry spasmodic cough often seized her. Her cramping and coughing spells were terrible to see.

After one of these attacks she would lie exhausted and unable to speak for a time. No organic disease was found, and treatment by suggestion was begun at the hospital. Her pains could all be relieved immediately, and she could get up and walk, although, from their long disuse, her limbs were very weak. The pain would be relieved, at first but a short time, but it staid away longer after each trial. It was soon found unnecessary to hypnotize her to relieve the pain. All that was necessary was to say, "I will take that pain all away," and laying my hand over the pain would say, "now it is gone—you have no more pain," and to the surprise of the patient herself she would be free from pain. Although it is now less than three months since treatment was begun, she gets up alone, walks to her meals, takes care of her own person, attends to the calls of nature alone, and from being a constant care night and day, she is a very independent person and is gaining strength rapidly.

Obstetrical cases are peculiarly amenable to this treatment,and I will cite one case: Mrs. M., aged thirty; primipara; labor pains very severe and fifteen minutes apart; presentation normal but no dilatation of os uteri. I told her labor would be very slow but I could put her to sleep so the pains would not hurt her. She proved an excellent subject, and, although the contractions came regularly, she said there was no pain about it, and she lay as if about half asleep. I hypnotized her about every six hours for three days, when I delivered her with forceps, and that operation was almost painless. The effect of the suggestion would seem in this case, to wear away in about six hours and have to be repeated.

I never use the words "mesmerize" or "hypnotize" to a patient, but simply say "I can put you to sleep and relieve that pain," and it must be said earnestly and with confidence. The patient is told that, if he will look intently at what I show him and keep his mind fixed on one thing, such as going to sleep—which he may repeat over and over to himself—in a few minutes his eyes will become heavy and he will not be able to hold them open, but they will close and he will fall asleep and then I will relieve all pain. In this way he is expecting just what you wish and, if you have his confidence, in a large percentage of cases you will succeed. A lead pencil is held about six inches in front of the eyes and when you see the effect of the eye strain you may say, "your eyes are getting red, they are beginning to water, the lids are getting heavy, you are getting sleepy—so sleepy, your eyes are going shut, you can not hold them open" and you keep suggesting just at the right time until you will see the pupils suddenly dilate, the eyes will close, and with a little tact the patient is under your control and you can relieve all pain.

I have often been surprised at the effect of the same suggestion when the patient was not hypnotized. Who has not used a placebo and seen it have just the effect suggested? It is well known that a hypodermic injection of water will often relieve pain, especially when a patient has been relieved by morphine used in this way. Our country is full of ignorant men who call themselves "Magnetic Healers," and if there was no demand for them they would have to go out of business. It is certainly true that they relieve pain and often encourage patients through long spells of sickness, such as typhoid fever, and they relieve many cases of so-called paralysis, yet their only stock in trade is

"suggestion." The christian scientist and the faith healer, although following slightly different methods, get their influence in the same way. If they can have some success, how much more can be accomplished by an intelligent physician who knows the laws of hypnotic suggestion and who knows when to apply them.

Obstetrical cases are good ones for the practice of suggestion, because usually there is rest enough between pains to get the patient's mind fixed on one thing, which is difficult to do while a severe pain lasts. I often find it better, in hypotizing a patient in severe pain, to first use a hypodermic injection of morphine and to follow it by suggestion, but this is unnecessary for a patient who has been often hypnotized. Undoubtedly the best effects of suggestion can be obtained on patients hypnotized, but very much can be done without this.

The objections to hypnotism are the unsavory reputation one is likely to gain by practicing an art not well understood in which so much influence is obtained, and, also, the length of time required.

To prepare a patient for a case of confinement or for a surgical operation, she should be hypnotized several times a week until it can be well done. It is always best to *do* something or to *give* something to make it appear reasonable to the patient that your words be true. It is not difficult, usually, to cause a nervous patient to have a certain number of hours sleep by giving a powder of bismuth, and at the same time suggest, *often* and *earnestly*, that it will surely have this effect. I sometimes wonder what pain *is* that it can be relieved by such means. I often tell a patient while hypnotized that at a certain hour the next day, or the next week, he will do some certain thing, and at just the hour stated he will do it. Yet before the time comes he cannot tell anything about it, and after it is done he cannot tell why he did it. The thought comes to him just as any impulse may come.

How many of our acts and beliefs may be due to unconscious suggestion? And how much physicians may accomplish by it none of us can tell, but surely it is a remedy of great power and needs further investigation.

# COMMUNICATIONS.

## UTERINE COMPLICATIONS, THEIR TREATMENT AND MISTREATMENT.*

P. C. PALMER, M. D., Kansas City, Mo.

The subject selected may be threadbare, yet the fabric is of sufficient integrity to justify the attempt to construct an article of perhaps some value from the remnant.

I shall pay particular attention to displacements of which we have a varied host, as regards the degrees of position:

First, *Versions* as theorized by our predecessors and the majority of gynecologists of the present day.

Second, *Flexions.*

Third, *Prolapsus.*

I assert that ante-version is a misnomer and release it from my category. Retro-version, the flexions and prolapsus we find in their varying phases, distinct and complicated. Retro-version being of comparatively slight importance, when uncomplicated, I shall not dilate on. It serves only as a stepping stone to worse troubles.

Though I assume all gynecologists are conversant with the different displacements, the different degrees of position are important as regards their effects and complications and merit due attention.

It is quite common to meet with cases where the fundus is so flexed as to rest on the bladder, pressing hard thereon, the os in its normal position, pointing backward at different degrees, and in some cases, pointing forward in a magnet shape, or even bent upon itself.

Next we find retro-flexion, in all the varying degrees which characterize ante-flexion, the fundus pressing the rectum to a greater or less extent, the os pressing on or near the bladder, down and forward at different angles, or backward, forming again the horse-shoe, or tightly flexed upon itself.

*Read before the Western Association of Obstetricians and Gynecologists, 1892.

The flexions not uncommonly take on the form of inversion, while more rarely, adhesions, or other causes, bring about lateral displacement.

Finally, the worst of the displacements is prolapsus, particularly when complicated with one or more of the other forms.

As regards causes for any of these conditions it would be an unpardonable infliction on your time and patience to attempt an explanation, there being nearly as many causes for these abnormalities as there are females suffering from the effects thereof.

With rare exceptions, by the time a flexion exists, or before, we have inflammatory troubles, an endometritis perhaps, but usually more extensive invasions have been made in the uterine tissues, and in the adjacent parts.

The cause and duration of any of these difficulties must largely determine the extent and physiological changes, and the resulting complications.

Although the flexions differ somewhat as regards position, they produce in their general effects a marked similarity, locally and constitutionally. To illustrate, an anteflexion, causes practically the same tension on the natural supports of the organ, and the same mechanical pressure, considering the degree of flexion, on the other pelvic organs, nerves, etc., as does the retoflexion.

With this exception, however, the former produces a more serious effect on the urinary organs, and the latter a correspondingly greater effect on the rectum with a resultant tendency to constipation.

These two points, while not infallible, are an excellent guide in diagnosis, when an examination is denied us, or previous to making the same.

Adding to this schedule of abnormalities, inversions, stenosis, elongated cervix and subinvolution, we have an expansive foundation for a list of complications which follow in variations most multitudinous:

Constipation.
Incontinence.
Cystitis.
Vaginitis.
Cellulitis, Peritonitis.
Metritis, Endo- and Perimetritis.
Salpingitis.
Ovaritis and inflammation of the relative parts.
Adhesion.
Ulceration.
Abscess.
Hysterorrhœa.
Granulations.
Amenorrhœa.
Dysmenorrhœa, Vicarious Menstruation.
Menorrhagia.
Menorrhœa.
Neuralgia and other neuroses.
Abdominal, pelvic, lumbar and other reflex pains.
Headache, Vertigo.
Melancholia, Nervousness and Hysteria.
Anæmia.
Leucorrhœa.
Acquired pulmonary consumption.
Pregnancy, Abortions.
Extra Uterine pregnancy, Hæmatocele.
Fibroids and other Tumors, such as Sarcoma.
Intraligamentous, Multilocular, Unilocular and Dermoid Cysts.
Cancers.

In tabulating this list of complications I do not in the least exclude the possibility of other difficulties producing symptoms and conditions which resemble those of uterine origin, any more than I would assert a woman has no organ but the uterus which disease may attack. Many of the difficulties above enumerated exist independently of those under consideration.

We may meet with almost any number of fibroma and myomatous tumors in an individual case, and strange to say the number does not increase the danger, for when a large number exists they are small. The single one being most mischievous. They grow slowly unless some complication arises, and stop at menopause, growing smaller, as a rule, thereafter.

The negress is more liable to these tumors than white women.

There is a close connecting link between these and sarcomatous and other malignant tumors which grow in the same locations. Any tumor which grows rapidly should be looked upon with suspicion. Cancer is the most fatal of all. Of this we may find any form save the scirrhus in the uterus.

The treatment must largely be peculiar to the individual case in hand, as each presents conditions essentially its own.

First and most important, is to correct the abnormalities in the most rational and conservative manner the case demands, whether it be by medicine systemically or locally, or by instrumental or surgical assistance.

To relieve suffering should be our first effort. Restore abnormalities to normalities, as best suits the individual case.

To express myself more definitely let me cite one case. Mrs. C. ; married 18 years ; three children; after allowing her troubles to grow constantly worse for fifteen years, presented on examination a

marked retroflexion, the ulcerated of pointing backward as far as the subinvoluted condition would permit, producing a closed magnet shape of the organ ; strong general adhesions ; ovaries three times the natural size ; the tubes greatly enlarged, indurated and tortuous, and general inflammation, cellular and peritoneal as well.

The slightest touch to the excoriated vagina was unbearable, to say nothing of the pain produced to the other inflamed parts, by gentle pressure, externally and internally. Constipation amounting almost to impaction, was of long standing. In short, every function of the body was disordered to an alarming degree. Seemingly a laparotomy was inevitable, but knowing their aversion to anything surgical I was forced to try other methods.

I used hot fomentations ; hot vaginal and rectal injections ; opiates and other systemics; local applications in the uterus; electricity ; elevating the fundus and retaining the position as far as gained by cotton tampons medicated, and as rapidly as possible as treatment progressed, breaking down the adhesions by instrumental and digital pressure. Though an early and continued improvement was manifest, many weeks elapsed before the patient could leave her bed. Soon after doing so, however, some indiscretion on her part in the way of work, brought on a serious relapse, from which, as would be expected, she improved more slowly than at first. Now, after eight months, she is around the house attending to household duties ; riding out in suitable weather ; suffering no pain ; the ovaries subsided to normal size ; no adhesions remaining ; constipation relieved ; appetite good ; skin clear ; is rapidly gaining flesh and the uterus is normal in position and size.

Ordinarily a laparotomy is to be urgently advised for the more speedy relief of cases of similar severity, and for the removal of abnormalities. Yet, as we know, nature can and does accomplish wonders, and we do well to imitate and assist nature as far as possible.

In the treatment of uterine displacements I *never* use a pessary, save in prolapsed or complicated cases, and *never* did.

In cases free from leucorrhœa or nearly so after improvement by treatment, instead of absorbent cotton I use antiseptic wool for tampons. This can be worn with as much comfort to the patient as cotton, and much longer—from three to five days or even more.

I almost always use electricity in any form of displacement, for more reasons than one; first, to shorten and strengthen the weakened and unnaturally lengthened ligaments and cords; second to assist, as it does, the stimulation to a healthier action, of natural tissues, and hastening the absorption of unhealthy or diseased parts.

Suturing for the retention of the uterus in overcoming flexions I call mistreatment, for certainly we gain our best ends by imitating nature. Naturally there are no adhesions, and, save in rare cases, producing this condition is a result to be avoided.

I briefly summarize the *mistreatments:* Of constipation is to continually dose the patient with cathartics without the removal of mechanical pressure or other obstructions.

Of incontinence in neglecting to relieve pressure and irritation and strengthen the muscular portion of the bladder, sphincter and urethra.

Of cystitis in neglecting to use hot fomentations, counter irritants, irrigation with hot boracic acid solutions, and diuretics, of which Apis mellifica is the chief.

Of vaginitis in neglecting hot water injections and soothing and astringent applications.

Of reflex troubles in treating symptoms instead of eradicating the disease.

Of dysmenorrhœa in relying on opiates, teas, hot slings, "goose grease and molasses."

Of leucorrhœa by using suppositories and vaginal capsules and other devices of doubtful origin and efficacy, leaving the uterus, the seat of the difficulty, unnoticed and untouched.

Of cellulitis and other inflammations of the pelvic organs in doing without counter irritants, hot fomentations, alteratives and intrauterine and vaginal applications.

Of lacerations, occlusions, stenoses, elongated cervix, cystic fibroid, and other tumors, abscesses, hæmatocele, etc., in tinkering to avoid an operation.

Of granulations in not curetting.

Of extra-uterine pregnancy in failing

to cause destruction by electricty and the use of ergot in the early stage, or to do laparotomy at the earliest discovery at any later stage.

Of suppressed menses, acquired consumption, hysteria, vertigo, melancholia, nervousness. Anæmia leucorrhœmia, headache of a character commonly described by patients as a "hot sensation on top of the head" or a "drawing pain in the back of the head," in treating the symptom without referring to the female organs as the seat of the disease.

Of menorrhœa and menorrhagia in doing without ergot in some form, and in hemorrhagics, without astringents locally,—tampons, cold applications, recumbent position and rest.

Of inverted uterus and pregnancy by mistaking them for tumors, hæmatocele, cystocele, etc., and treating or operating accordingly.

Of miscarriage, without removal of every portion of the fœtal tissues, membranes, etc.—in all cases where an abortion is inevitable, and without proper local after treatment.

Of malignant tumors, vicarious menstruation, retro-latero or ligamentous hæmatocele in neglecting palliative treatment or an operation for prolonging life, and giving a very unfavorable prognosis.

## ERRORS THAT MAY ARISE IN MEASURING THE LENGTH OF THE LOWER LIMBS.*

J. S. WIGHT, M. D.†

So long as surgeons consider it important to overcome the shortening of the lower limb after fracture of the femur, it will also be important to remove the sources of error in the determination of the amount of this shortening.

What are the sources of error in measuring the length of the lower limb? A brief statement of these points is not out of place, since there is a difference of opinion in regard to them, and since there is thought by some surgeons to be important to make a lower limb as long as it was before its femur was broken. The facts relate to the comparative lengths of the lower limbs, as determined by measurement.

Now what are the requirements of a true and faithful measurement? It must be made by a reliable tape-line; one that will not stretch by pulling on it. It must be from symmetrical points of bone,—one on each side, corresponding to the one on the other side. It must be made with the lower limbs parallel and meeting the transverse axis of the pelvis at the same angle. It must be made with the lower limbs in the same degree of flexion. Finally, it must be made without prejudice, for the simple purpose of establishing the truth.

The usual point of measurement above is the superior anterior process of the ilium. I sometimes measure from the top of the trochanter major. The points below are the lower ends of the internal and the external malleoli. Other points may be used, but these will answer.

The following errors may arise from the attitude of the lower limb: Abduction of the lower limb shortens its measurement. Adduction of the lower limb lengthens its measurement. Hence, an error of measurement will arise, when one lower limb is adducted, and the other is abducted. Then let the lower limb whose femur is broken be adducted, and the other abducted, and the real shortening will not be detected. In a case of this kind there would be a scientific error. Flexion of the lower limb shortens its measurement. Extension of the lower limb lengthens its measurement. Hence, let the lower limb in which the femur has been broken, be extended and let the other limb be flexed, and the actual shortening will not be detected. Now let one lower limb be abducted and flexed, and let the other be adducted and ex-

* Read before the Brooklyn Surgical Society, September 21, 1893.

†Professor of Operative and Clinical Surgery at the Long Island College Hospital, Brooklyn, N. Y.

tended, and the error in the measurement will be greater still.

Tilting the pelvis, as any one may see, acts like adduction and abduction on the comparative measurements of the lower limbs. Tilt one side of the pelvis downward, and the lower limb on that side is relatively abducted, and the one on the other side is relatively adducted. Hence, tilting the pelvis may cause an error to arise in the comparative measurement and lengths of the lower limbs.

The normal a-symmetry of the lower limbs is another source of error in their measurement: If the longer limb has its femur broken, it may be easy enough to make it of the same length as the other limb; but if the shorter limb has its femur broken, it may be impossible to make the limb as long as the other.

There is still another source of error possible in measuring the length of the lower limbs. It arises in this way: A traction weight is applied to the lower part of the limb, in order to overcome the overlapping of the fragments; or the surgeon takes hold of the leg and foot and pulls downward for the same purpose. The measurement is made during the time of this traction, or at the time of this pull, and is perhaps put down as a clinical fact. The traction, or the pull, is applied until the injured limb becomes as long as the other.

In my clinical lectures, when at the bedside of the patient with a broken femur, I have often demonstrated how a limb could be elongated by traction in the manner mentioned. I had attributed the effects to the fact that the lower fragment had been brought downward into a better reduction. A record was made of the measurement at the time of the traction or the pull. Also, a measurement was made and recorded before any attempt had been instituted for the purpose of reduction of the fragments. After union of the fragments had taken place, and the patient had got up and gone about, another measurement was made and recorded. These measurements varied: The shortest measurement was the one made before the reduction of the fragments; the next measurement, the one depending on the traction or pull, was the longest; and the one made after the treatment was complete and the patient had been divested of apparatus, as we may well believe, was intermediate in length between the other two measurements.

In time the full significance of these facts came to my mind: that the lower limb can be elongated by means of traction or pull. In order to test this conclusion in a proper and trustworthy manner, I resorted to experiment. I obtained a dynamometer to measure the traction applied in pounds, and used it to pull upon the normal lower limb. The pull to be applied in each case was fixed at thirty pounds. The limb was measured both before and after the pull, and the length in inches was noted together with the age and occupation in each case.

THE MEASUREMENT OF TWENTY NORMAL LOWER LIMBS, BEFORE AND AFTER THE APPLICATION OF A TRACTION OF THIRTY POUNDS.

| | Occupation | Age | Limb | Before pull | After-pull |
|---|---|---|---|---|---|
| 1 | Stable-boy | 16 | Left. | 33.2-8 in. | 33.6-8 in. |
| 2 | Stone-cutter | 23 | Left. | 34.2-8 in. | 34.6-8 in. |
| 3 | Laborer | 35 | Right. | 33.6-8 in. | 34.2-8 in. |
| 4 | Sailor | 27 | Right. | 33.6-8 in. | 34.1-8 in. |
| 5 | Hack-driver | 50 | Left. | 29.3-8 in. | 29.5-8 in. |
| 6 | Farmer | 30 | Right. | 33.3-8 in. | 33.5-8 in. |
| 7 | Laborer | 52 | Right. | 33.2-8 in. | 34 in. |
| 8 | Carpenter | 35 | Right. | 31.4-8 in. | 32 in. |
| 9 | Photog'pher | 24 | Left. | 34.4-8 in. | 35 in. |
| 10 | Laborer | 39 | Left. | 35. in. | 35.3-8 in. |
| 11 | Laborer | 34 | Right. | 32.4-8 in. | 32.6-8 in. |
| 12 | Sailor | 40 | Lett. | 34.6-8 in. | 34.7-8 in. |
| 13 | Bartender | 21 | Right. | 33.6-8 in. | 34.3-8 in. |
| 14 | Seaman | 30 | Right. | 34.4-8 in. | 35 in. |
| 15 | Laborer | 25 | Right. | 33.6-9 in. | 34.1-8 in. |
| 16 | Laborer | 19 | Left. | 31.4-8 in. | 32 in. |
| 17 | Seaman | 50 | Left. | 34 in. | 34.3-8 in. |
| 18 | Seaman | 44 | Left. | 34 in. | 34.4-8 in. |
| 19 | Engineer | 38 | Right. | 33.4-8 in. | 33.6-8 in. |
| 20 | Seaman | 20 | Right. | 35.2-8 in. | 35.4-8 in. |

The twenty cases above tabulated give the following conclusions: The greatest lengthening of the lower limb after a traction of thirty pounds was six-eighths of an inch; and the average lengthening was $\frac{3}{8}\frac{3}{8}$ of an inch, or nearly one-half of an inch.

Other cases were measured, showing lengthening of the lower limb under traction, but the above twenty cases were all that I recorded. I am reasonably certain that a large number of cases will show a similar result. In fact, I have often verified this lengthening in cases of fracture of the femur. When the fragments have united, apply the tape-line, with the lower limb under traction, and then stop the traction, with the tape-line still applied, and it will be more or less slackened.

The traction was applied only during the time it took to make the second measurement; what effect it would have if it were kept up for three or four weeks I know not, but am convinced that it would be greater than has been noted above.

A traction of ten or fifteen pounds, kept on for four or five weeks, would doubtless have as great an effect as thirty pounds kept up for one minute. In fact, ten pounds can do more work in four weeks than thirty pounds can in one day: hence, we have not obtained the maximum effect in the lengthening of the lower limb by means of traction.

The general conclusion then would be that the traction-weight used in the treatment of a fracture of the femur will lengthen the lower limb, irrespective of the removal of the longitudinal displacement. If this is so, since bones cannot stretch, the change must take place in the joints: the ankle-joint must be excluded: the hip-joint may be effected to some extent; but the chief cause must be found in the knee-joint: that is, the ligaments of the knee-joint stretch under the traction we put upon the lower limb.

There is a modifying circumstance which accompanies the traction. Traction tilts the pelvis downward on the side where it is made, and that tends to shorten the measurement of the lower limb, as we have seen;—hence, the lengthening may be even greater than we have made it.

The opinion we are obliged to form on this subject is: That a measurement of the lower limb at the time of the action of the traction-weight is incorrect, incompetent, misleading and irrelevant, as a piece of surgical evidence. To make a measurement reliable and admissible, it must be made after the removal of the traction-weight. Hence, it must happen that all statistics that have been founded upon such measurements are without any practical value whatever. This must be so since the traction-weight vitiates the correctness of the measurements.

Here we may mention one other source of error in the measurement of the lower limb, under any circumstances: It is found in the personal equation. Does the surgeon desire the full expression of the facts in the case? Then let him see to it that he removes every source of admitting error in his professional work. Does the surgeon desire to make it appear that he can get better results than those which others can obtain? Then the best thing for him to do is to lay aside all ambition except that which leads him forward in the search for the truth.

## STATISTICS CONCERNING EYE DISEASES IN THE ROCKY MOUNTAIN REGION.*

JOHN CHASE, M.D.,† Denver, Colorado.

I have often been asked by patients and physicians if I did not consider Colorado climate particularly trying to the eyes. The impression is prevalent that those forms of eye disease which are induced or aggravated by bright light, heat and dust, are more commonly met with here than in the Eastern States.

In conversation with physicians long resident in the Rocky Mountain Region, I have been struck with the almost universal prevalence of the opinion that conjunctivitis, trachoma and ulcerations of the cornea are marked peculiarities of this region. The traveling public are so thoroughly impressed with this idea that I have often met among eastern visitors the expressed fear of contracting eye disease during a short residence in our climate. The ubiquitious dark glasses are worn by hosts of these tourists as a defense against maladies which are supposed to lurk in our dust and sunshine. I have even heard it asserted that the bountiful supply of oculists in our Western country is an evidence of an effort of nature to supply an antidote for disease. If I am not mistaken the records of this Society show that the experience of oculists is in accord with the sentiments I have expressed.

* Read before the Colorado State Medical Society, 1893.

†Professor of Ophthalmology and Otology, University of Colorado.

For several years I have been skeptical of the truth of this generally received belief, although during my first two or three years residence in Denver I accepted as a fact that which everyone seemed to believe. So far as I am aware, there have been no carefully compiled statistics to guide us in drawing scientific conclusions as to the relative frequency of various eye diseases, East and West. I am fully aware of the errors which may creep into comparisons such as I shall here make. I know that the number of cases on which I base estimates is small; I admit that methods of recording cases differ,—for example, one observer may report 1,000 cases from 300 or 400 patients, while another would allow but one record for each patient, still I believe that a comparison can fairly be made after eliminating, so far as possible, all causes of error and dissimilarity in records.

A comparison of diseases other than those I mention would be interesting, but the chief object of this paper is to discover if the Rocky Mountain climate predisposes to certain diseases of the eye. As an evidence of the youthfulness of our population I have also called attention to the number of cases of senile cataract East and West.

For the purpose of comparison I have placed in the table figures relating to conjunctivitis, acute and chronic, trachoma, lachrymal troubles, iritis, ulcers of the cornea, and senile cataract. From the various reports at hand, I have selected as fairly representative of different sections of the country, the following: Presbyterian Eye and Ear Hospital, Baltimore; Ophthalmic and Aural Institute, New York, for years 1887, '88 '89; St. Mary's Free Eye and Ear Infirmary, Detroit; Illinois Charitable Eye and Ear Infirmary, Chicago, 1890; Wills Eye Hospital, Philadelphia, 1890; Denver cases during the years 1892 and 1893.

If reports from further South had been used, elements such as race characteristics would have required attention.

I refer to three consecutive reports from New York Hospital to illustrate the fact that the ratio of diseases in any given institution is quite constant.

My own report is made from the record of private patients during 13 months ending June 1st, 1893, and comprises 984 cases.

The results would have been almost identical had I used clinical cases, but my private record was more reliable and therefore preferred.

| | Acute Conjunctivitis | Chronic Conjunctivitis | Trachoma | Lachrymal | Iritis | Ulcer Cornea | Senile Cataract |
|---|---|---|---|---|---|---|---|
| Presb. E. & E. Inf. Balt... | 20.8 | 20.8 | .9 | 3 7 | 2.6 | 20.1 | 5.5 |
| O. and A. Inst. N. Y. 1887. | 6.1 | 13.2 | 4.2 | 2.3 | 1.4 | 3.1 | 3.5 |
| " " " 1888. | 9.2 | 13.2 | 3.9 | 2.4 | 1.5 | 2.9 | 2.3 |
| " " " 1889. | 4.7 | 16.1 | 5.4 | 2.3 | 1.3 | 2.9 | 1.5 |
| St. Mary's Inf., Detroit... | 5.9 | 2.7 | 5.6 | 2.3 | 2.3 | 2.4 | 1.2 |
| Ill. Char. E. & E. hosp. '90. | 5.8 | 5.4 | 5.9 | 2.1 | 3.2 | 4 2 | 2.7 |
| Wills Eye Hosp. Phila. '90. | .9 | 6. | 1.4 | 1.9 | 1.7 | 2.7 | 2.05 |
| Denver, 1892 and 1893..... | 5.8 | 2.5 | 2.9 | 3.6 | 3.9 | 3.1 | 1.1 |

From an examination of the table it will be seen that Colorado is peculiar fortunate in the matter of conjunctivitis, as only one report gives a lower record in the acute form and none in the chronic. In the reports from Baltimore and Philadelphia no division is made on the basis of acute and chronic, but the total of the two varieties exceeds that of Denver. I wish to call particular attention to the fact that we have this year in Colorado, suffered from an epidemic of acute conjunctivitis. More than four-fifths of the cases in my report were met with after June 1st, of the present year. The epidemic became so prevalent in the city schools that the authorities in one or two instances asked for an examination of the pupils and took measures to limit the spread of the disease. Notwithstanding the presence of this epidemic the ratio of conjunctivitis for Colorado is exceedingly low.

In trachoma, Colorado surpasses two of the reports and stands below the rest.

Inflammation of the lachrymal tract seems to be very prevalent in this locality, if the table is to be taken as a guide. I will add that the result conforms to my experience during seven years residence in Denver.

In diseases of the iris also, Colorado shows an unpleasant preeminence, but it will hardly be urged that this disease is much influenced by climate.

In ulceration of the cornea there seems to be a very constant ratio for all of the reports.

Senile cataract does not appear to be common here, and I believe for the same reason that we do not see many cases of glaucoma, namely, the youthfulness of the population. The Western population is notably young. The pioneer's of the

early '60's are not yet old men, while the great mass of our citizens, who have come West during the last 15 years, have been under 35 years of age.

During the year I have seen but two cases of true snow blindness, and in common with other observers believe this disease to be rare.

It is difficult to explain these figures, but I believe that fuller notes and larger collections of cases will confirm the conclusions drawn from this small table. All know how irritating to the conjunctiva are our numerous sandstones, and all have experienced the unpleasant effect of riding over our plains or mountains in the glare of an unclouded sky. Personal experience would lead most people to think the common impression right and my tables wrong, but I believe that careful observation will confirm my conclusions.

I offer the following as a possible explanation. In this dry climate and at this altitude, the conjunctiva tends more rapidly to recovery than it does in the East where moist nasal catarrh is so common. I freely concede that the causes for conjunctivitis are more abundant here than in the East. It is possible that hyperæmia is more prevalent, although it would be difficult to establish that fact. What I do maintain is that of the cases of conjunctivitis and trachoma requiring treatment we do not see so large a ratio here as in the East; while in lachrymal troubles and ulcerations of the cornea we have to deal with only an average number of cases.

# SOCIETY REPORTS.

## AMERICAN MEDICAL ASSOCIATION, SECTION OF NEUROLOGY AND MEDICAL JURISPRUDENCE.

[ABSTRACT OF PAPERS.]

ADDRESS BY THE CHAIRMAN, Dr. C. K. Mills, of Philadelphia.

THE INFLUENCE OF SPECIAL SOCIETIES AND SECTION WORK ON THE DEVELOPMENT OF NEUROLOGY IN AMERICA.

The writer suggested the advisability of limiting the time for discussion to five minutes, except in the case of the reader of the paper who should close the discussion. He referred to the excellent work done by the Philadelphia Neurological Society, stating that more than one-half of the work done by that society would not have seen the light had not the society been in existence, giving this as an example of the advantage of such societies. The American Medical Society can best advance by allotting special work to sections. The appointment of commitees to do special work has been of great value. But too many isolated cases have been reported and papers have not always been well prepared in the work of these societies. A great advantage of small societies is that they secure definiteness of aim.

ON THE WEIGHT OF THE BRAIN,

by Dr. Henry H. Donaldson, Chicago, Ill.

It is important to determine how far we may draw inferences from the weight of the brain. In a large number of examinations it has been shown that the weight of the brain in the male is greater than in the female; that the weight of the brain in insanity is not unusual except in cases of wasting disease; that the brain wastes slightly in old age. These observations, however, are taken from the unfortunate classes. It is shown that the brain increases rapidly in size from birth up to seven or eight years and more slowly up to fifteen or twenty. Then for the next few years there usually occurs a slight falling off in weight, which gives place to an increase up to 35 or 40, the weight remaining constant for 10 or 15 years, then decreasing. It must be remembered, however, that these facts are gained from an examination of the dead and not the living subjects, therefore the curve which represents the course of brain growth cannot be taken as representing growth of the individual brain. If we could study the

favored classes we might find different results. Brain growth is especially rapid during the first year. Cells and their prolongations are the structural elements of the nervous system. All nerve cells are formed before birth and the brain increases after birth by the enlargement of the elements already present, and not by the formation of new elements. In the human brain the white substance is but little less than the gray, but we do not know what the physiological interpretation of the medullary substance is. The granules in the cortex and other localities are undeveloped nerve cells which by growth are transformed into the characteristic ganglion cells. The conditions of growth must be delicate, so two individuals starting with nerve cells of the same weight at birth, arrive at maturity with very different brain weight. The size and number of the elements and relative abundance of the medullary substance must be the next step in the interpretation. Race, age, sex, stature, bodily weight, mental condition, individual development, cause of death, autopsy are all factors to be considered.

DYSPEPSIA AS A NERVOUS DISEASE, OR INDIGESTION IN ITS NERVOUS ASPECT AND RELATIONS,

by Dr. C. H. Hughes, of St. Louis.

The purpose of Dr. Hughes' is to place on record the fact which is now quite generally recognized, that dyspepsia, as we generally encounter it, is more frequently a secondary disease than a primary one, secondary as to degenerative or exhaustive changes in the central nervous system ; and the illustrations in the paper are drawn from the class of people who furnish us our patients as dyspeptics, and from some portions of the rest of the animal kingdom. It is a well-known fact that hogs never have dyspepsia; that when you come among trained animals, however, you first find the elements of dyspepsia, owing to the animals being subjected to a certain extent, to those habits of life and environment which bring about the neuratrophic condition from which dyspepsia arises as a secondary disease.

NOTES ON THE TREATMENT OF EXOPHTHALMIC GOITRE.

by Dr. J. Madison Taylor, of Philadelphia, Pa.

Dr. Taylor takes up the subject of exophthalmic goitre as understood at the present time, reviews its relationship to other vascular disturbances, associated with enlargement of the thyroid, as myxodema, cretinism and acromegalia. He does not see that at present the thyroid physiology warrants any large measure of hope that we shall treat this malady through thyroid juices, as in the case of the other disorders mentioned, and yet promises to explore this field later. He confines himself chiefly to the analysis of a number of cases long under his care, some of them for many years, and most of whom are well, summarizing the means through which these were improved. The treatment of maladies which demand but little constant supervision and yet require prolonged watchfulness, is more or less difficult and unsatisfactory because such cases wander away, will not persist in treatment, and from their nature of unhopefulness, have a tendency to fall into the hands of other medical men and have their treatment changed, etc., make it difficult to pursue any consistant plan, even with those inclined to be faithful. He takes the ground that this disorder is capable of much more hopeful treatment than is generally thought; that most cases are enormously improved, if rightly handled; that many may get well.

The question of treatment is chiefly considered from the standpoint of his own experience. This consists in:

1. Regulated rest, with carefully graduated activities as time and circumstances warrant, systematic measures directed to the upbuilding of the general health, careful attention to nutrition, recognizing the trophic elements in the disorder.

2. Careful attention to vascular conditions, which are most noticeably at fault and which demand the most constant treatment. This consists of varying measures, regulating vaso-motor activities, as well as loss of nervous force through the easily disturbed nervous balance. This is done through attention to the skin from the surface by means of certain remedies which seem to exert a control over the constant tendency to vaso-motor neuroses, both superficial and deep.

3. To search out constitutional defects and remedy these, eliminate accidental poisons, either diathetic or temporary, eliminate toxines, as of internal sewage

poisoning which has a very direct bearing.

4. The regulation of the nervous or emotional balance by careful attention to the habits and environment of the individual, carefully regulating, so far as possible, the habitual emotional strains and the possible ones, making much of moral teachings to those whose will power and mental equilibrium are gravely at fault constitutionally, and as inevitable entanglements due to months and years of suffering and susceptibilities.

5. A careful consideration of such measures as are regarded as specific, as electricity, of which much has been made by many writers, but whose value consists chiefly in the system and encouragement which is thereby exerted over the disordered emotional states.

Finally, a summary of the cases under observation when the original paper was written in 1888, and the report of a number of others seen since then, and a careful review of the symptomatology, and recent means of treatment.

### SUGGESTIONS ON THE TREATMENT OF LOCOMOTOR ATAXIA,

by Dr. Daniel R. Brower, of Chicago.

Some cases may be cured and some may have the rate of progression considerably impeded. If the disease is recognized in the preataxic stage, rest for three months should be the foundation of the treatment. Iodide of potassium in large doses, fluid extract of ergot in full doses, and galvanism are of value. Hypodermic injections of morphia are most valuable to relieve paroxysms of pain. Carefully guard the digestive organs; alcoholic stimulants and sexual intercourse should be prohibited. When the second stage or the stage of incoördination has been reached, when the disease usually progresses rapidly, ergot will sometimes prevent the progression. Suspension is of service, continued as long as possible, five to fifteen minutes. In this stage the injection of chloride of gold and sodium is advisable, at the same time employing phosphite of zinc and arseniate of sodium, also galvanism; no benefit from internal administration of any preparation of silver. Cold bathing is of value; hot baths contra-indicated. The pains of the second stage are met by morphia; sometimes phenacetine, antipyrine, etc., answer the purpose better. Patients can be taught to regain some degree of coördination by the practice of standing with feet close together, with eyes closed. If the patient stands in the bath tub and has cold water poured on his spine, he will more speedily regain this coördinating control. Bladder needs attention to avoid possible cystitis. Use hypodermic injections of morphia to stop gastric crises. In the third stage use tonics; galvanism to the spine and faradism to the surface; injections of cerebrine and other animal products have thus far in the writer's experience proved unfavorable, yet may admit further trial.

#### DISCUSSION.

Dr. T. D. Crothers recommended Turkish baths and said they sometimes effected an apparent cure.

Dr. C. H. Hughes, of St. Louis, suggested that the diagnosis was incorrect in cases of apparent recovery, and that the correct diagnosis in such cases should be multo-neuritis. He considered recumbent flexion superior to extension.

Dr. F. R. Fry, of St. Louis, stated that a great deal of trouble arose from the extravagant claims of quacks to cure this disorder. There is the greatest discrepancy in recommendations of practitioners. We have all of us seen cases of genuine tabes do well, but as there are many cases of apparent or temporary improvement under various methods of therapy, we should be careful about formulating conclusions as to the proper treatment.

Dr. Brower, concluding the discussion, said that he was satisfied that some cases of locomotor ataxia, if the treatment is commenced in the preataxic stage and is constant and proper, can be greatly improved, and perhaps some recoveries may take place.

### HEMIPARAPLEGIA, REPORT OF A CASE COMPLETELY RECOVERED AFTER ONE YEAR'S DURATION.

by Dr. L. Harrison Mettler, of Chicago.

The writer concludes that the correct explanation of the case indicates that we may have hemiparaplegia from a lesion in the lower part of the cord in which the anæsthesia and paralysis appear upon the same side of the body, but that further investigations are needed on this point, though the writer feels sure that the text-books are somewhat too dogmatic in asserting that in all cases hemiparaplegia

is a paralysis of one-half of the lower part of the body with anesthesia of the opposite half.

AURAL VERTIGO, MENIERE'S DISEASE,

by Dr. L. Harrison Mettler, of Chicago.

Medical literature abounds in cases wherein a sudden attack of vertigo associated with loss of hearing was diagnosed as hemorrhage into the labyrinth, without further investigation into the correctness of the inference, but vertigo as a mental phenomena seems to be of far too complicated a character to presuppose so simple an origin. If the views of Spitka and Starr are true in regard to the sensory paths in the medulla, they bear strongly in favor of this sensory motor theory of vertigo. Every indication points to the fact that we must look for the center of equilibration not in one particular part of the brain, but in the harmonious action of the various sensory and motor centers one upon the other. Meniére himself seems to have believed that only the semicircular canals are affected in true Meniére's disease. He, however, declared the canals to be the cause of cerebral symptoms on the strength of a single observation, and even that observation was not conclusive as to that particular case. Much confusion has arisen in regard to this affection, disease in any part of the internal ear and even of the middle ear, has been termed Meniére's disease, though Meniére himself restricts it to the semicircular canals. Gower strongly supports the labyrinthine origin of vertigo, but his proofs are very inadequate; though we admit the implication of the semicircular canal in aural vertigo, it still remains a difficult matter to explain the vertiginous symptoms and loss of hearing upon his hypothesis in all cases. The semicircular canals in the sharks have been removed without obtaining any disturbance of movement. There is no regular correspondence between the amount of deafness and the intensity of the vertigo with total loss of hearing in Meniére's disease. All known methods of diagnosis prove that the nerve itself and not merely the internal ear is affected. Physiological experiment shows that simple pressure does not cause total loss of hearing, when no injury is done to the cochlea, and no case has ever been reported in which the cochlea was primarily affected with consequent involvement of the canals and vertigo. Hence in Meniére's disease the writer concludes that the lesion must concern the whole labyrinth or lie entirely outside of it. There is little doubt about the central nature of the disease in many of its aspects. The sense of irritation may sometimes be in the semicircular canals just as sometimes it may be in the eye or in the stomach, but the immediate cause of the vertigo cannot be there, and in view of the few pathological data at hand, we are not justified in assigning all cases of vertigo to an unknown and undemonstrable lesion of the internal ear.

A METHOD OF LOCALIZING POINTS IN THE HEMISPHERICAL GANGLIA,

by Dr. William Fuller, of Grand Rapids, Michigan.

The writer stated that he had hardened a brain with great care, separated the lateral halves, and each half was carefully sliced by a gauge, so that the slices were three-sixteenths of an inch thick, perpendicular to a line in the long axis of the brain. By this means he had obtained photographs of 74 vertical transverse cuts of the brain. Dr. Palmer presented a model of the brain made in the manner indicated, to show the anatomy of the brain.

Dr. Palmer stated that in 1877 he made a craniectomy for the relief of idiocy, an account of which was published in the *Canadian Medical and Surgical Journal* of 1878; he stated that he was the first to perform that operation. The operation was ridiculed in both America and Europe at the time, but has since been claimed as originating with European surgeons.

A CASE OF SUBCORTICAL CYST OF THE LOWER PART OF THE ASCENDING PARIETAL CONVOLUTION; OPERATION; RECOVERY.

by Dr. Theodore Diller, of Pittsburg, Pa. and Dr. J. J. Buchannan.

A thorough history of the case is given by Dr. Diller. Nearly all the important symptoms of intracranial growth were present. Headache, vomiting, vertigo, convulsions and paresis. From the history of the case it was evident that a lesion was located in the left Rolandic region, involving principally the hand center. The absence of sensory symptoms seems to indicate that the lesion was

situated anterior to the Rolandic fissure, and from the fact that paresis preceded convulsions, the lesion seemed probably a subcortical one. Thus the means were given for determining the proper position of the opening of the skull. Operation was done by Dr. Buchannan. The relative method of Thane was employed to locate the fissure. Dr. Buchannan employed a thin sheet of aluminum, cut in the form of a segment of a circle, having an angle of 67 degrees and a radius of three and three-eight inches and molded to fit the average skull, when its straight sides are applied respectively to the median line and to the part of the scalp corresponding to the fissure of Rolando. While the result of the operation fell considerably short of an entire cure and is in a measure disappointing, yet it was followed by distinct and unmistakable benefit to the patient. It is too early to tell what the ultimate result will be. The case offered strong evidence in support of the view that the ascending frontal convolution is exculsively related to motor function. The cortical representation of the forearm and hand are located in the ascending frontal convolution; the cortical subdivisions of the arm area are related to each other as follows in the ascending convolution, that for the shoulder highest, elbow, wrist, fingers below in the order named; center for the thumb is located in the ascending parietal convolution, closely adjacent to posterior bed, and a little below that for the fingers. The theory that a subcortical lesion is apt to produce paresis before convulsions finds confirmation in this case, and the general principles of localization as enunciated by Horsley, Seguin, Mills and others are well exemplified in this case.

SURGERY IN THE INSANE

by Dr. C. B. Burr, Pontiac, Michigan.

This paper contains a collection of cases illustrating phases of surgery which come under the eye of the hospital alienist, including the gynecological operations; also two cases of melancholia in each of which the operation of trephining had been done, showing the futility of trephining. A case is given indicating some of the great difficulties encountered in the care of old dements. Suicidal attempts are far from infrequent. Case illustrating the curative effect of operations *per se*, well known to alienists and which of late surgeons are beginning to recognize. Herniæ and perityphlitis are relatively frequent in the insane, but often pass unoticed.

In the discussion of this paper, Dr. H. N. Moyer held that the element of consent was extremely important, especially where surgery of a very radical character and which is not as yet well grounded—as for instance the removal of tubes and ovaries where there is no apparent local disease—for the benefit upon the general nervous system, is employed. He referred to the fact that shock is comparatively slight in operations upon insane persons notwithstanding their general low nutrition.

Dr. James G. Kiernan, of Chicago, held that the position of superintendent of an insane asylum was a quasi legal one and that he is the guardian of the patient, and under such circumstances has the right to give consent for the patient for an operation, and especially is that true in an emergency case; the removal of healthy tubes and ovaries is not likely to produce a permanent improvement. The counter irritation may produce a temporary improvement, but such operations are not justifiable. He referred to the improper operation of a so-called great apostle of the American operation or orificial surgery, and its frequent evil results.

Dr. G H. Rohe, of Catonsville, Md., held that a marked improvement did follow such operations and that in many cases they were justifiable. He believed the opinion given by a legal member of the Pennsylvania board of lunacy was not worth the paper upon which it was written, that is regarding the question of consent, which is the most important point touched upon in the discussion; in intervals of lucidity insane patients could properly give consent; but an insane person in the eyes of the law is not an individual and cannot give consent, but the speaker believed that a legal guardian appointed by the court is a guardian of the individual's person; he thought the liability of the operator to a suit for malpractice was sufficient protection.

Dr. Moyer thought that the question was whether this operation of removing the ovaries and tubes was justifiable at the present time in a given case, and what the general opinion of the profession was as to how many will be cured by this procedure.

THERAPEUTICAL USE OF STATIC ELECTRICITY.

by Dr. G. F. Lydston, of Chicago, Ill.

The writer held that the use of static electricity in medicine has been too closely restricted to the more advanced neurologists. He has found it a very reliable agent in his office practice and valuable especially in neurasthenia, particularly in the forms associated with brain fag and sexual hypochondriasis. The application of the static current to the spine has seemed to have a marked stimulating effect upon the genito-spinal centers. Some eleven years ago the writer suffered from profound neurasthenia which developed atrophic changes in the muscles of the hands. A cure was effected by static electricity. He has used the static current in a number of cases with a greater or less degree of success. In some instances it seemed to have no effect whatever. He has, however, seen no cases in which it seemed to be injurious, although his experience would lead him to believe that in some delicate and neurotic patients the agent should be used with a certain degree of circumspection.

Dr. L. C. Gray, of New York, said that too much had been expected from the use of static electricity at first, that it had proved disappointing, and there was a revulsion of feeling against it and it had been largely discontinued, but that very probably it was coming into use again. The improved machines of the present day are a great advantage; results have been surprising in certain cases; especially has it proven useful in cases of muscular atrophy.

Dr. Daniel R. Brower, of Chicago, called attention to the usefulness of this current in cases of chorea, and described his method of application, by placing the patient on an insulated stool and applying the current for from ten to fifteen minutes.

Dr. Lydston stated that the art did not seem to be exceedingly well defined at present; the question of the element of hypnotic suggestion should not be given too prominent a part; the effect of a current in chronic inflammatory troubles with the joints has been excellent; the current has been applied heretofore empirically, and there has been no great attempt made at the classification of the various indications; he does not know where to look himself for a clear presentation of the indications and methods of application of static electricity; with regard to his own case he was firmly convinced that he was cured through the medium of static electricity; he does not believe, however, that he had true progressive muscular atrophy.

SODIUM ARSENIATE IN THE NEUROSES,

by Dr. Harold M. Moyer, of Chicago.

Arsenic in nervous troubles ranks very high as a therapeutic agent. The objection to the use of Fowler's solution, that is the arsenite of potassium, hypodermically is that it is exceedingly irritating. Arsenic when exhibited beneath the skin has a far less toxic effect than when administered by the mouth. The fact of the arseniate of potassium giving rise to no local irritation allows the use of a much larger dose than of the arsenite. He has exhibited an arsenic equivalent in the arseniate of sodium, of 40 to 60 minims of Fowler's solution at a single dose, and it is a common practice to give an equivalent dose of 80 minims of Fowler's solution as the initial injection. It is necessary in order to prepare accurate solutions for hypodermatic use, to subject the salt to a temperature of about 300 degrees which drives off the water of crystallization. The method in short is worthy of more extended trial.

INSANITY AMONG CONVICTS

by Dr. M. V. Ball, of Philadelphia.

The paper presented illustrates some of the types of insanity found among persons convicted of crime. When we recognize that "every society deserves the criminals it has" we will endeavor to correct the evils that in a large part cause crime, and treat our malefactors not with a spirit of vengeance, not with a visitation of justice, not as sinners, but merely as obstructionists whom society must place under restraint or remove to a place where they can be of service instead of hindrance; then only will the penal question reach solution. Our present mode of justice is childish. What would be thought of the suggestion that a chronic maniac should be sent to an insane asylum for one year and then released unconditionally, and then after he had killed some one, again sentence him for a definite term of one or more years? The danger to society alone should be considered and the professional

criminal placed in durance vile until cured, if that result is possible, or permanently if the danger to society is ineradicable, and wholly as a protection to society and irrespective of his sanity or insanity, his moral responsibility or irresponsibility.

WHAT SHOULD CONSTITUTE RESPONSIBILITY IN THE MEDICAL SENSE, IN INSANITY?

by Dr. Landon Carter Gray, of New York.

The object of the paper was to call the attention of the medical profession to the fact that great injustice is likely to be done to insane people by basing the view of their insanity upon the proposition that if a man is able to understand the nature, quality, and consequences of an act, he is legally responsible for such an act. The doctor most emphatically declared that the question of legal responsibility should be determined, not by laws, but by facts. Medical science demonstrates the fact that a diseased condition of the brain giving rise to mental aberration, permits of no half way ground in judging of sanity. Periods of remission cannot reasonably be called "lucid intervals," as is often done. After classifying the types of insanity which have been demarcated up to the present time as: the presence of hallucinations; the presence of delusions; the co-existence of organic disease of the brain; traumatic causation; causation from excessive use of narcotics; and the mental disturbances occurring from derangement of the organism induced by disease of non-nervous viscera, Dr. Gray called attention to the fact that in paranoia, mania and melancholia the reasoning powers and the memory are usually intact, yet the patient has undeniable hallucinations and delusions, and under the influence of those delusions and hallucinations commits acts for which he should not be held legally responsible. He cites the case of the paranoiac Dougherty, who imagined himself the beloved of Mary Anderson and that the world was conspiring to keep him from her and, in pursuance of this delusion, murdered Dr. Lloyd of the Flatbush Insane Asylum, and was planning to kill about a dozen public officers whom he believed to be in the conspiracy. Yet he declared himself sane and asserted that he knew the nature, quality, and consequence of his act. He was probably pronounced insane because his mania was so palpable, although some doubt prevailed in the public mind as to his insanity. The doctor concludes by saying that the only safe test of the legal and testamentary responsibility of a man lies in an answer to the simple question: Is he insane? If he is, he is not legally responsible, and this question can only be properly decided by competent physicians, not by fine spun theories of lawyers. Common sense must be applied to such cases rather than metaphysical definitions of mental aberration.

DOUBLE LESION OF THE BRAIN; CEREBRAL CYST AND CEREBELLAR TUMOR.

by Dr. Edward B. Angell, of Rochester, N. Y.

The object of the presentation of this case was to indicate that it undoubtedly showed an increase in development on the right side which had had to take upon itself the left brain function, and then in addition to that, not only were the centers corresponding to the speech center of the left side hypertrophied, but the surrounding cortical structure had been increased in area and character; and it is important to consider whether benefit cannot be derived by such indirect exercise.

Dr. James G. Kiernan, of Chicago, called attention to the case of the reeducation of the speech center in an adult, the recovery being complete, but a second attack produced aphasia. The autopsy showed that there was an old apoplexy destroying the left side, and the second attack destroyed the right. Dr. Kiernan doubted whether cases of epilepsy were curable.

RECENT DEVELOPMENTS IN GUNNERY OF INTEREST TO THE MEDICAL JURISTS.

by Dr. J. N. Hall, of Denver, Colorado.

He said that newly introduced explosives are rapidly replacing black powder; he described the two most commonly used of these products, the American wood powder and the Schultze powder; the staining from wood powder is much less distinct than from black, and the staining from the Schultze powder is less marked than even the wood powder described; neither of the two powders mentioned ignited cloth or blotting paper at so great a distance as did the black powder.

Dr. Harold N. Moyer, in discussing the paper, called attention to the fact that

the length of the barrel of the weapon should always be a factor in making up tables, and stated that there was always leakage of gases in revolvers; another interesting point would be not only as to the kind of powder, but also as to the amount of fulminate in the fixed ammunition, and as to the manner in which it is put into the cartridge, whether fine grained or practically in a solid mass.

THE SECRETARY, called attention to the fact that in some instances, in the case, for instance, of a double barreled rifle, the barrels were not of the same size, and that might have a bearing in criminal matters.

SENSORY SYMPTOMS OF THREE SYPHILITIC CORD CASES,

by Dr. Frank R. Fry, of St. Louis, Mo.

The purpose of the minute account of these cases given was that the writer felt, in the light of Dr. Erb's recent investigations, we are warranted in making very careful clinical records of our syphilitic cord cases in order that we may formulate a symptomatology which will help to more readily differentiate these cases.

In discussing the paper, Dr. L.C.Gray, of New York, held that the views of Dr. Erb that there are always exaggerated reflexes, have not met with success, and are disproved by these very cases of Dr. Fry. The speaker held that it was better to admit that we have not as yet discovered any pathognomonic symptoms by which we can detect a disease, than to be deluded; but that there are symptoms in quite a number of intracranial cases which, if taken early, would make it possible to relieve the disease and prevent its progress; he also believed that some such symptoms can be discovered in regard to spinal syphilis, but that they have not as yet been found, and, therefore, these cases are very valuable as a disproof of some of the assertions of Dr. Erb.

Dr. Moyer called attention to the necessity of these minute investigations, that physicians have generally been too careless in making diagnoses and as too hastily classing a disease as tabes or paraplegia, etc.; he thought that the grouping of fifty or one hundred cases such as Dr. Fry has described, would do more to elucidate the matter than anything else.

LESION OF THE RIGHT TEMPORO-SPHENOIDAL LOBE,

by Dr. W. J. Herdman, of Ann Arbor, Mich.

The writer stated that this lobe of the brain has been spoken of as being a latent region, destruction and irritation of which produced no special and distinctive phenomena. This region of the human brain is surrounded with darkness. The paper gives a very minute history of a case, which the writer at first diagnosed as one of arterial embolus obstructing the left anterior cerebral artery. The autopsy revealed that the regional attack had been due to a hemorrhage very extensive anterior to, and at the lower extremity of the right lateral cornu. Softening followed involving the hippocampus major at its lower extremity and the anterior extremities of the superior, middle and inferior temporal convolutions. The writer believes we are justified in the asumption that as far as any symptoms observed in this case can be justly referred to the lesion in the right temporal lobe, they tend to show that its function is of the same nature for the left side of the body that Ferrier has found the left temporal lobe to be for the right, a cortex center for hearing and taste. There is necessity for a systematic and thorough examination in detail of all the sensory motor tracts in every case of central lesion, after a definite plan which should, wherever circumstances permit, be rigidly carried out.

In the discussion of this paper, Dr. Charles K. Mills referred to several similar cases which appeared to demonstrate that the left upper temporal region is most particularly developed for word sound, and the right has a minor degree of development of the same function and takes on the function of the left in part but not entirely, in case of the destruction of the former.

HEMIANOPOSIA AND CERTAIN SYMPTOM GROUPS IN SUB-CORTICAL LESION,

by Drs. Charles K. Mills and G. E. de Schweinitz, of Philadelphia, Pa.

This paper deals chiefly with reference to the diagnosis of the locality of the lesion. The observations of the paper were confined strictly to cerebral cases. Seguin's three cases were summarized, which he regarded as due to lesion of the

outer edge of the thalamus and of the internal capsule in its caudle parts. The first case of the paper showed right lateral hemianopsia, absence of Wernicke's symptom, dyslexia, temporary right hemiparesis, and Jacksonian epilepsy. Case two: right lateral hemianopsia, absence of Wernicke's symptom, dyslexia, right hemiparesis, partial right hemianæsthesia, partial word deafness and word blindness. Case three: right lateral hemianopsia, absence of Wernicke's symptom, temporary aphasia, dyslexia, right hemiparesis of spastic type, probable word blindness. Case four: left lateral hemianopsia, left hemiparaplegia and hemianæsthesia partial, aphasia temporary. Epilepsy, Wernicke's symptom. Case five: right lateral hemianopsia, absence of Wernicke's symptom, temporary right hemiplegia, persistent hemianæsthesia. Case six: left lateral hemianopsia, left hemiplegia. Case seven: right hemianopsia, right hemianæsthesia. Case eight: right lateral hemianopsia, absence of Wernicke's symptom, doubtful; slight right hemiparesis. Case nine: left lateral hemianopsia, absence of Wernicke's symptom at first, paresis of both legs, later right spastic crural monoparesis. Two cases were given which were probably cortical, one having a typical left lateral hemianopsia and the second right hemianopsia with absence of Wernicke's symptom.

Another case was given of right lateral hemianopsia followed a year later by left lateral hemianopsia, absence of Wernicke's symptom, macular vision retained, changes in color since, loss of sense of location.

Case also reported which would seem to teach that we may have either functional or organic disturbance of the word symbol center of the same character as that which produces hemianopsia when the half center for general vision is destroyed on one side of the brain.

AMERICAN INEBRIATE ASYLUMS

by Dr. Thomas D. Crothers, Hartford, Conn.

The essayist gave a history of the Binghamton establishment; managers of asylums who teach dogmatically the nature of inebriety and its only true remedies are not very far along in their scientific work, and asylums which claim large percentages of cures from certain means and remedies are not worthy of confidence. Inebriety is the most complex neurosis of modern research. The gold cure specifics so-called, are followed by an increased number of insane among those who have used the treatment, which is something to be expected as the more powerful the narcotic used to stop the drink symptom the more certainly insanity and profound degenerations of the brain centers will follow. The asylum care and treatment of inebriates began first in this century and has grown and extended to all civilized nations of the earth. American asylums have developed the disease theory and the practical character of physical treatment in institutions, beyond that of any others in this field. Asylums in this country represent nearly all stages of development and early growth, from infancy and childhood with its feeble conceptions and infantile efforts, to the boastful assumption and over confidence of youth, on to the dawning truth of early manhood when reason and judgment begin to reign. A few of these asylums discern similar great truths, which may be stated with confidence as ideals toward which there is a rapid movement. Inebriate asylums must take the place of jails and station houses. Inebriate asylums should receive the incurable inebriates and make them self-supporting and build them up physically and mentally. Inebriate hospitals should receive the recent cases and place them in the highest conditions of enforced health and vigor, and thus return a large number to health and sobriety again. Inebriate hospitals should be self-supporting when once established. They should be managed on scientific business principles like military training schools. Inebriate hospitals should be built from money raised by taxes on the sale of spirits, on the principle that every business should be obliged to provide for the accidents which grow out of it. These are realities which every inebriate hospital is approaching and which all experience point out as practical in the near future. The inebriate hospitals of to-day are only in the infancy of their work, contending with great opposition and prejudice, misunderstood, condemned and working against innumerable obstacles. There is an intense personality in inebriate hospitals. Inebriate hospitals and their work are the great new lands which only a few settlers have

reached. They are calling to us to come and occupy, and thus help the race on in the great march from the lower to the higher.

LAWYER'S CRITICISMS OF EXPERT TESTIMONY,

by Dr. Clark Gapen, of Omaha, Neb.

The expert is an important factor in the various litigations that arise. As at present conducted, the trial of a case involving a medico-legal question is a mere farce as compared with the trial of a cause involving a pure question of law. Lawyers sometimes like to pose as learned in medicine. The expert should be selected by the court as advising it, and wholly with reference to his special knowledge of the question involved. We should teach medical jurisprudence in colleges properly. The so-called chair of medical jurisprudence usually teaches nothing but the mummery of some text book of ancient times. But the proper way is to give a forecast of what the student will encounter in the future. He should be taught to be frank, truthful, direct, plain and non-technical. Students go forth unequipped in this regard. Another cause of the disrespect of medical expert evidence is the common custom of participating both as counsel and witness in the trial. The court might properly take testimony as to the qualifications of the expert. A good way would be to have lists handed in by each side and let the court choose from the lists. The expert should avoid invading the province of the jury and giving an opinion on the case. The proper course is to put a hypothetical question for the expert to answer.

The following papers were also read:

1. Insanity in the Aged, by Dr. Frank T. Norbury, of Jacksonville, Ill.

2. Acute Mental Symptoms in Children, by Dr. Harriet C. B. Alexander, of Chicago, Ill.

---

A MODEL FOR CUPID.—"Well," said the artist, sharply, to the tramp who had entered, "what do you want here? Hurry with what you have to say."

"Sir," replied the tramp, with inborn dignity, "I did not come here to be insulted. I merely thought to step in and inquire if you had any model for your valentine Cupid. If not I desire to apply for the position."—*Lippincotts.*

A HARD SUBJECT.—The constitutional inability of some people to grow fat under the most favorable circumstances found an excellent example in the person of Mr. Ezra Sprawley, of Alderville. His wife's comical distress over the fact at last found vent in a remark which has passed into a by-word in that New England town.

"I used t' think," said the good, energetic woman and admirable housekeeper in a pensive mood one day, "I *used* to think that food, cooked proper an' dealt out liberal, couldn't help puttin' some flesh on folks's bones.

"An I c'nsidered, previous to weddin' with Ezra, that 'twas owin' to the fact that his sister Jane was a scant pervider that he looked so terrible peaked; but I misjedged her—an' him, that's the truth.

"Why, jest look at him now," said Mrs. Sprawley, dolefully, directing her visitor's gaze to the figure of her gaunt spouse as he stood in the barn door-way; "just look at him, thin as a match. Why, my land!"—here she passed to the portion of her remark which became historical:

"I've fed three hearty meals a day, reg'lar, to that man, for up'ards of fifteen years, an' he aint ever give the *fust evidence* of 'em."—*Youth's Companion.*

ENGLISH AS SHE IS WROTE.—"In the week immediately preceding her death, Elizabeth Fuidge, while suffering under the illness of which she died and *in the immediate expectation of death who was then staying at Weston-super-Mare for her health*, told Mary Fisher to take the keys of the dressing case and box and to keep the same."

# THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, OCTOBER 7, 1893.

## EDITORIAL.

### ECHOES FROM THE PAN-AMERICAN CONGRESS.

Among the subjects considered by the section of hygiene, quarantine, etc., none was more important than that involved in the following resolution emanating from and ably supported by Dr. Shakespeare of Philadelphia, Dr. Cyrus Edson of the New York Board of Health, and others:

*Resolved*: "That it is the sense of this section that in view of the prevalence of Asiatic cholera in Europe at the present time, and the constantly increasing number of foci of infection, immigration from European countries in which cholera exists should be temporarily suspended, as this action affords, in our opinion, the only certain means of averting a threatened invasion by the disease of countries of the American Continent."

Notwithstanding the importance of this resolution and the fact that it would have exercised a potent influence with our national health authorities in encouraging effective measures to bar out all visitation of an epidemic that has made fearful ravages in many sections of Europe during the past two summers—our exemption from which is the reward of the efforts and precautions of zealous and intelligent health authorities—this resolution failed of favorable consideration by the International Executive Committee to which it was referred. The reasons for this failure are not plain. Few Americans doubt the wisdom of the policy it suggests. Had it been submitted to a vote of the Congress there is no doubt it would have had a large majority in its support.

The chief opponent of the resolution was from over the seas, whence, for a long time we have been getting a great number of people we do not want, and who have not contributed to our moral, social, political or physical well doing.

Just the extent of the influence of Mr. Ernest Hart, the able editor of the *British Medical Journal*, in defeating the resolution we will leave for those to determine who were personally present. We fail to appreciate Mr. Hart's logic.

Our National Congress in framing our quarantine law, incorporated a provision giving to the President the discretionary power "to prohibit in whole or in part the introduction of persons and property from such countries or places as he shall designate, and for such period of time as he may deem necessary whenever, by reason of existence of cholera or other infective or contagious disease" in a foreign country, there is serious danger of the introduction of the same into the United States, despite the quarantine defenses. The resolution in question was in support of this provision of our quarantine law. It was intended as a second to this provision by an able body of representative American physicians voicing the sentiment of the profession and of our people.

The Pan-American Congress was made up of representatives of the Americas, and should have been permitted to speak for America uninfluenced by English opinion. Cholera is indiginous to India, and all England has done or is doing for India is to garrison it. Let her put a military cordon about the birthplace of cholera and keep it within its native territory.

With our quarantine authority centralized we know where to look for its execution and whom to hold responsible for failures. Such resolutions, coming from the leaders of medical opinion, strengthen the hands and direct the conduct of those in authority. That we have not had a serious visitation of cholera has been largely due to our quarantine authorities under the zealous and intelligent direction of Surgeon General Wyman.

The politico-economic phases involved in the prohibition of immigration we do not attempt to discuss. Their consideration belongs more properly to those holding down chairs in our halls of legislation. There are facts, however, which cannot fail to press themselves home upon the American citizen and his law-makers (the few who are Americans). They cannot escape giving thoughtful consideration to the facts that we have more than 2,000,000 idle men in the United States; that this idle class is being added to monthly by immigration; that in the one month of July last it received an addition of 47,000 immigrants exclusive of those coming in through Canada and Mexico. As the cholera scare increases in Europe, immigration will increase unless American governments as a matter of self-protection impose restrictions. The true way to keep cholera from gaining a foot-hold in the United States is to prevent it being brought here by immigrant or merchant ships.

While cholera has not gained a foothold in London, it has extended its ravages over many sections of Europe and England. London's comparative exemption is due to the vigilance of her health authorities and to improved sanitary regulations. Where it has once gained a hold the stamping out process has not been a success.

We will let our English brother speak in his own emphatic way. "My thesis is that cholera death is a violent death, an unnatural death, a preventable death; that the very existance of epidemic cholera, not to say endemic cholera, is a reproach to the nation and to the community in which it exists. Being a violent death its prevalence is due to ignorance or apathy, which, from the dimensions of a blunder, easily develops into the proportions of a gigantic crime. Cholera death can be prevented and ought to be prevented."

All this is what the intelligent of the medical profession and the people of our country claim—that it can be prevented and that this is the more effectually done by preventing the landing on our shores of immigrants from infected countries. To fail in such precaution would be a "gigantic crime."

Yet another resolution urging measures of sanitary precaution failed of adoption, though urged with earnestness and a strong array of arguments by the most eminent of American authorities upon the subject of the epidemics by which we are threatened and from which we have the most to fear. In this instance it is surprising that an educated profession should be behind the people—far less zealous in their care for the public health. The resolution in itself is easy reading, and will impress the reader of average intelligence with its value as a sanitary measure—it urged the thorough disinfection of every piece of baggage or article belonging to an immigrant or to any member of the crew of immigrant ships. Against this could be interposed only the influence of steamship companies. When once the steamship companies are made to understand the certainty and thoroughness of the inspection to which they will be subjected, as a matter of self-protection they will be more rigid in their own sanitary precautions. If this work is a burden it is certainly one more easily borne by rich steamship companies than is a typhus fever or a cholera epidemic by dense communities.

The lesson should be impressed that there is an element of murder by willfully and knowingly carrying of disease among people free from it, and that it is equally criminal to permit such carrying where prevention is possible. The extent of our coast, the number of ports of entry, the wealth and activity of our commerce, only render the more urgent and important rigid measures. It is preventive measures we should adopt and press to successful execution, and not wait until an epidemic gets its grip upon our people. Our immunity thus far should not be permitted to lull our people and health authorities into that sense of security which will leave open the avenues of ingress. Important as is our commerce, it can be brought under such regulations as will not impose useless burdens or be productive of special embarrassment. All the commerce of the world brought into our ports will serve us little purpose if there is to come with it disease and death.

Among our own people regulations are imposed to prevent the transmission of epidemic or contagious diseases from one neighborhood or community to another, or along the lines of our inter-State commerce. These regulations are submitted to by our own people uncomplainingly, though they impose great hardship upon families and entire communities. It is recognized that the greater hardship would be to permit the disease to extend the territory of its ravages.

How She Kept her Word.—"Do you remember that rich and romantic Miss Rocques, who used to say she would never allow a man's poverty to prevent her from marrying him?"

"Yes, indeed, but I never thought she meant it."

"She did, though. She's going to marry a man who doesn't own a dollar in the world, and is deeply in debt."

"Is it possible? Who is he?"

"I don't remember his name,—some sort of a broken-down earl her mother picked up in London."—*Detroit Tribune.*

Old Subscriber (to editor).—Can you lend me five dollars?"

Editor.—"We cannot."

Old Subscriber.—"Paper not doin' much, eh?"

Editor.—"Well, we're holdin' our own."—*Lippincotts.*

How a Cold Affected Him.—A little boy caught a very severe cold while his mamma was out of the city, and on her return rushed up to her, and throwing his arms around her, cried, "Oh, mamma, both of my eyes is rainin' and one of my noses won't go."—*Lippincotts.*

A Pennsylvania testator recently provided that an interest in land devised to his daughter should, in case of her death without issue, be "reversible to my right consanguinary heirs.'—*General Digest.*

# TRANSLATIONS.

## ONE HUNDRED RADICAL OPERATIONS FOR INGUINAL HERNIA PERFORMED AFTER THE METHOD OF BASSINI.

Previous to 1891, the author, C. Nicoladoni, had performed the radical operation for hernia, only in cases where the ring was much enlarged, or where adhesions had taken place, making it impossible to wear a truss.

After the above mentioned year, and since he had seen the brilliant results following the method of Bassini, he has operated on one hundred cases, the results of which he now places before the medical profession.

He calls attention to two principal steps in the operation which produce such satisfactory results: First, the application of the ligature high up on the peritaneal covering of the sac. Second, the reconstruction of the posterior and anterior wall of the inguinal canal, by uniting the abdominal muscles with Poupart's ligament, and the accurate closure of the external oblique muscle.

Of the 100 radical operations there was one death after 16 days, due to pyæmia, the result of two septic ligatures; 5 healed secondarily, and in 94 union took place by first intention. The youngest patient was 2 years, the eldest 65. The patients were not instructed to wear any trusses after the operation.—(*Wiener Med. Presse. 1893.*)

## TREATMENT OF TUBERCULAR DISEASE OF THE HIP JOINT.

Dr. Zitzke (Inaugural dissertation), has made a study of 51 operated cases, occuring in the practice of H. Schmid in Stettin during the years 1887 to 1891, and concludes that resection of the hip joint affords best results in tubercular coxitis.

The result of these cases is as follows: The operation was performed in 47 cases, of which 11 died, making a mortality of 21.5 per cent.—4 directly referable to the operation; 31 were entirely cured, equalling 61 per cent.; 4 improved and 5 unimproved. Seventeen of the 31 cures had good use of the operated limb, 11 moderately good, and 3 not so good. In a later investigation of the 40 cases discharged, the author found 22 entirely cured, 4 having a small superficial fistula; of these 26, 3 had excellent use of the limb, 11 good use, 6 moderately good and in 6 there seemed some difficulty in deciding. Seven had died; 1 from a local return, 5 from general tuberculosis, 1 from diphtheria and 7 were lost sight of.

The author comparing these statistics with those of other methods of treatment, particularly of iodoform injections, concludes that resection, if not exactly an ideal treatment, is, however, the most rational for this disease. He considers the operation indicated as soon as the disease has become fully established, particularly if crepitation can be demonstrated under narcosis. He places stress upon the removal of all tubercular matter when the resection is done, using the same care as he would in removing carcinomatous disease.

The after treatment is worthy of some mention. Extension is rarely resorted to; the limb is abducted, placed in a splint and bandaged. As a rule the patient is allowed to sit up on the third day and to get up on the fourteenth day, and is then encouraged to bathe and exercise.

As soon as possible the cane should be laid aside and walking encouraged by using the entire foot. A high shoe is never resorted to, the object being that the pelvis, on the operated side should incline downward. In order to avoid any flexion of the limb, the pelvis is raised during the night; lastly, exercises are systematically carried ont, such as mounting steps, kneeling, sitting, etc.—*Centralbatt für Chirurg,* 1893.

# ABSTRACTS.

## IMMUNITY AGAINST "CHOLERA."

In a recent paper, Dr. Klein, has opened up a new question with regard to bacterial poisons, a question which before him was partially already touched upon by R. Pfeiffer. Klein showed that when emulsions of various cultures grown on agar agar, prepared in the same manner as that employed by Haffkine in his "anticholeraic vaccinations," are injected into the peritoneal cavity of guinea-pigs, the result is the same as that following on a similar injection of an emulsion of an agar agar culture of cholera-bacilli. Klein used cultures of cholera bacilli, of the vibrio of Finkler, the bacillus coli, proteus vulgaris, the bacillus prodigiosus, and the bacillus of typhoid fever. By means of intraperitoneal injections of non-fatal doses, he rendered the animals refractory against further intraperitoneal injections of fatal doses, and he found that "the refractory condition produced by intraperitoneal injections of a non-fatal dose of one of the above six species holds good against all the other five." He argues from his experiments that while employing agar agar culture in this manner, the bacilli are used without their specific poisons, and that the pathological changes produced in the animals under such conditions are due to the "protoplasmic" or "intracellular" poison of the micro-organisms; and that probably the "intracellular" poison of these different species of bacteria is identical, since they mutually protect the animals. He further contends that a notable difference exists between the "intracellular" poison and the toxins elaborated by the bacilli in the culture medium, and concludes that though protected against such "intracellular" poison by such methods of vaccination as practised by Haffkine, the animals are not necessarily protected against the toxins elaborated in the culture medium (for example, gelatine) by the bacilli. In proof of this, he mentions that guinea-pigs which have survived the intraperitoneal injection of fatal doses of Haffkine's *virus fort,* when subsequently inoculated intraperitoneally with old liquified gelatine cultures of cholera bacilli promptly succumb.

Hitherto it was generally believed that an immunity artificially produced against the bacillus itself was sufficient to protect the animal against the specific infection produced by such bacillus, and so far as immunity is concerned, no distinction was drawn between the "intracellular" and the "metabolic" poisons. Klein's researches suggested so many new questions of vital importance, that it seemed inviting to examine this matter more fully, and to investigate whether an immunity acquired against the "intracellular" poison will also be efficacious against a true specific infection with the same bacillus.

*A priori* it would seem sufficient to protect the animal in such a manner as to enable the organism to destroy the bacillus itself, thus giving the latter no time or possibility to elaborate its toxins, and no doubt for all practical purposes where preventive inoculation is likely to come into play, this would be all that is required. It is well known that in some cases it is difficult, in others even impossible, to immunise an animal against the specific toxin, administered in lethal doses, although small doses of such toxin introduced by subcutaneous or intraperitoneal injections will readily render the animal refractory against the microbe manufacturing the toxin. This is so well known that a few examples only need be mentioned here. Gamaleïa has observed that guinea-pigs immunised against the vibrio Metschnikovi remain as sensitive to the toxin of this vibrio as non-immunised animals. Charrin and Gamaleïa further have shown that this is true also for the bacillus pyocyaneus and its toxin, and Selander and Metschnikoff have confirmed the same for the microbe of hog cholera and its toxin. Issaeff, lastly, has demonstrated that rabbits immunised against infection with the diplococcus pneumonia are, nevertheless, extremely sensitive against the toxin of this microbe.

It is thus evident that the acquired immunity against certain bacteria is not necessarily accompained or followed by a resistance against the specific poisons of

such bacteria, although these poisons were employed to establish the immunity. These facts may explain Klein's remarkable result, that animals resistant against large doses of highly virulent comma bacilli succumbed to large doses of old liquefied gelatine cultures, since it is quite possible that the gelatine cultures used by him contained lethal doses of the specific poision in addition to the bacilli present.

We have repeated some of Klein's experiments, and extended them in various directions, and have obtained results which may throw some fresh light on the important question of the relation of immunity to the "intracellular" specific poisons. As might have been expected, we have been able to confirm most of Klein's results.

I. In our own experiments we have employed the bacillus prodigiosus, bacillus pyocyaneus, and the vibrio of cholera. Agar emulsions of any one of them injected into the peritoneal cavity of guinea-pigs proved fatal, the appearances being identical with those described by Klein. Whatever microbe was used for intraperitoneal injection, it was found that in all the fatal cases the bacilli had multiplied enormously in the peritoneal cavity, were almost invariably present in the heart's blood, and, when looked for, also found in the pleural cavity. This shows that death in all cases was due to a true infection and not an intoxication, as Pfeiffer assumed. The multiplication of the proliferation are a *sine qua non*, and are especially striking when small doses of agar emulsions are used. In regard to cholera infections. Gruber and Wiener have already pointed this out. A similar proliferation also invariably followed on fatal intramuscular or subcutaneous inoculations of the agar emulsions. On the strength of these facts it seems at least doubtful that the fatal lesions should be the result of poisoning by "bacterial proteins." It is more reasonable to assume that we are dealing here with a true infection.

(2) According to Klein, sterilised agar emulsions intraperitoneally injected produce the same result as the agar emulsion, namely, peritonitis and death. As far as cholera is concerned, R. Pfeiffer agrees with him. Gruber and Wiener, on the other hand, disagree, and come to the conclusion that the "protoplasmic" poison of the vibrio has nothing to do with the typical infection. Our own experiments in this direction were limited, but we have failed to produce fatal results with sterilised emulsions prepared from half an agar culture of bacillus pyocyaneus and vibrio of cholera, although one-fifth of living agar emulsions sufficed to kill a guinea-pig. We have not followed up this matter, as it lay somewhat outside the purpose of this research, and we are thus unable to reconcile the contradictory statements of Klein and Pfeiffer on the one hand and of Gruber and Weiner on the other.

(3) As might have been expected from Klein's results, we found that the intraperitoneal injections of an emulsion of an agar-agar culture of the bacillus prodigiosus prepared in the same manner as that employed by Haffkine in his inoculations will immunise rabbits and guinea-pigs without fail against similar inoculations with agar cultures of the bacillus pyocyaneus. It is immaterial whether the immunising emulsion is given intraperitoneally or subcutaneously, or whether it is living or sterilised; the result is the same, and the animal will resist a subsequent peritoneal inoculation of a scraped agar culture of the bacillus pyocyaneus.

(4) *A fortiori* a subcutaneous or intraperitoneal injection of an emulsion of an agar culture of the bacillus pyocyaneus, sterilised or living, will immunise a guinea-pig or rabbit against a subsequent similar intraperitoneal injection of an agar culture of the bacillus pyocyaneus.

(5) This, then, is in full accordance with Klein's experiences, and requires no further comment. Now, if it be a question merely of one "intracellular" poison against another "intracellular" poison, a guinea-pig or rabbit immunised by the above methods might be expected to succumb to an inoculation with old but living bouillon cultures. It was found, however, that such animals resisted large doses of such cultures, which killed control animals in eighteen hours.

(6) Rats are insusceptible to anthrax, but extremely susceptible to an infection with the bacillus pyocyaneus. It was found that our white rats would resist enormous doses of anthrax cultures (eighteen hours old) scraped off agar agar,

and made into an emulsion, while they would die after even small doses of similar emulsions prepared with bacillus pyocyaneus, whether they had previously been treated with intraperitoneal injections of anthrax emulsions or not. From these results we must conclude that anthrax grown on agar agar contains no "intracellular" poison, or that if it does its "intracellular" poison does not immunise against that of the bacillus pyocyaneus. It should be mentioned, however, that though the anthrax cultures used were only eighteen hours old, there were already spores in many of the bacilli, although most of the bacilli were quite free from spores.

There seems to be some special relation between the so-called "intracellular" poison and the pathogenic property of a bacillus, or, differently expressed, if a bacillus is pathogenic to a certain species of animals, then its "intracellular" poison is also pathogenic. Again, if the "intracellular" poison be the same for various species of bacilli, then the lethal doses should be identical for the various bacterial species. Now, it is well known that rabbits are comparatively resistant against cholera infection, and we found that, in spite of injecting large doses of Haffkine's *virus fort* (a whole tube) intraperitoneally into even young animals, they were none the worse after it although one-twelfth of a culture of cholera bacilli would kill a guinea-pig. On the other hand, one-fifth of a culture of bacillus pyocyaneus intraperitoneally injected was invariably fatal to rabbits. Again, it required much larger doses of "prodigiosus emulsion" than of "pyocyaneus emulsion" to kill rabbits; the agar cultures least. And also in the case of guinea-pigs "pyocyaneus emulsion" was found to be more virulent than "prodigiosus emulsion." It appears, therefore, that there is something besides the "intracellular" poison which decides the fatal issue. In fact it seems that it is the active metabolism of the bacillus by which the specific toxic substances are produced in the body of the animal. Why is it that the one bacillus should protect an animal against another or several others, we do not attempt to explain. It may be a purely local immunity. How important the local predisposition and resistance are we know from various experiments, amongst which we may refer to those of Blagovestchensky and Roger.

(7) While testing this question still further, we immunised guinea-pigs by Haffkine's method, and found that subsequently they resisted intraperitoneal injections of large doses of bouillon and even liquefied gelatine cultures of comma bacilli. So far as gelatine cultures are concerned, our results are in direct contradiction to Klein's. Our gelatine cultures were two month's old, and it is possible that they did not contain so much toxin as Klein's. Large doses were used, however, half a culture for each inoculation, which killed the controls in less than twelve hours. If we are justified in assuming that bouillon and liquefied cultures contain the specific cholera toxin, from our experiments it would seem that previous inoculations of non-lethal doses of agar culture emulsions immunise also against the comma bacillus *plus* its metabolic products. Moreover, we found that the converse holds good, namely, that,

(8) By means of subcutaneous injections of small doses of virulent bouillon cultures of comma bacilli, guinea-pigs are immunised against intraperitoneal injections of large doses of Haffkine's *virus fort.* We must conclude, therefore, that, after a typical infection short of death, the animal will easily resist the "intracellular" poison.

(9) The result was in no way modified when, instead of living bouillon cultures, cultures heated up to 70° C. for ten to thirty minutes were used for subcutaneous vaccination. Animals vaccinated in this manner comfortably resisted large doses of the *virus fort.* In most cases the cultures were not filtered; the issue, however, was the same when cultures were employed for protective vaccination which had been deprived of their bacilli by means of filtration through a Hankin's porcelain filter. Guinea-pigs treated with such filtered cultures proved resistant against Haffkine's *virus fort.* It is, of course, doubtful whether our filtered or heated cultures contained the true cholera toxin. Large doses of such sterilized cultures, which had been grown under ordinary aerobic conditions, failed to produce death. Others (van Emergen, Cantani, Nicati and Rietsch, etc.) have succeeded, by means of filtration through Chamberlain's filters, in obtaining more active

toxic bodies. Hueppe and School again claim to have separated from cultures in eggs and choleraic dejecta extremely toxic substances. Gruber and Wiener have thrown considerable doubt on Scholl's results, at least so far as the toxin extracted from eggs inoculated with coma bacilli is concerned, and Huppe's method of extraction of toxins from choleraic dejecta is naturally open to criticism. The whole toxicology of cholera is at present in a chaotic condition, and as yet we know but little of the nature of cholera toxins, and so long as the results of various investigators are so contradictory criticism is impossible. We have assumed that our bouillon cultures contain the metabolic products of the cholera bacillus. It is worthy of note, however, that even 5 c.c. of such cultures sterilized by heat injected intraperitoneally failed to produce death. Gruber and Wiener similarly found that the sterilized peritoneal exudation of animals which had succumbed to intraperitoneal injections of cholera bacilli, even when injected in comparatively large doses, had no fatal effect, while equal or smaller doses of the non-sterilized exudation produced death at least at the first transmission.

That a protection against an infection with coma bacilli can be effected by inoculation with sterilized or filtered bouillon cultures has already been shown by others, notably by Vincenzi, Gamaleia, and Klemperer, but we have further shown that this immunity holds good also against the inoculation of the intracellular poison or Haffkine's *virus fort*.

All these experiments throw some doubt on the too narrow or distinctive conception of an intracellular poison, and it seems that within certain limits the virulence of the poison varies with the pathogenic property of the bacillus—that is, with the power of its metabolic toxin. Immunity against bouillon cultures means also immunity against agar-agar cultures—that is, the "intracellular" poison and *vice versa*; and immunity against the latter implies immunity against gelatine cultures, unless, perhaps, these cultures contain an excessive dose of toxin. Immunity produced by any one method employed by us—that is, Haffkine's method or preventive inoculation with bouillon cultures, living or sterile, filtered or not—amounts to immunity against any other form of inoculation, at least so long as we are dealing with the same bacillus.

It is no doubt difficult to explain why an intraperitoneal or subcutaneous injection of "prodigiosus agar emulsion" should protect rabbits or guinea-pigs against an intraperitoneal injection of pyocyaneus agar emulsion, but that it is hardly a question of one intracellular poison against another seems probable from the fact that it is possible, by means of intraperitoneal injections of old bouillon cultures of the bacillus prodigiosus to render rabbits immune against intraperitoneal injections of "pyocyaneus agar emulsion." The whole matter requires further study on broader lines, and this must be left for future investigation.

(10) The following observations also compel us to regard a too dogmatic or systematic distinction between "intracellular" and metabolic poisons in their relation to immunity with some doubt. Guinea-pigs are immunised against "cholera" by various methods, and their serum used to immunise other guinea-pigs. It was found that (1) the serum of an animal immunised by Haffkine's method will readily immunise another guinea-pig against Haffkine's *virus fort;* (2) it will also immunise against intraperitoneal injections of large doses of virulent bouillon cultures. Similarly it was found that the serum of one of us inoculated by Haffkine's method will immunise guinea-pigs against intraperitoneal injections of Haffkine's *virus fort* or virulent bouillon cultures in large doses. It may here be mentioned that it is quite immaterial whether the serum be injected subcutaneously or intraperitoneally, and that large doses of serum (4 to 6 c.c.) often caused severe and extensive ulceration of the abdominal wall when injected subcutaneously. In one case a copious intraperitoneal injection caused death in two days, the animal suffering from the usual symptoms of a subacute intoxication. In all cases, whether our own serum or that of immunised guinea-pigs was used, large doses of serum (2 c.c. and more) caused the animals to be ill and feverish for some time (three or four days). There was loss of appetite, and the coat was rough, and the animals hid themselves in the straw. It is is quite possible, therefore, that the immunising serum contains

some active, if not the specific toxic substance.

11. It was further found that the serum of guinea-pigs immunised by repeated subcutaneous injections of bouillon cultures heated to 65° or 100° C. will immunise others against intraperitoneal injections of large doses of Haffkine's *virus fort* or virulent bouillon cultures.

One of us was treated by subcutaneous injections of virulent bouillon cultures, while at the same time large doses of sterilized bouillon cultures were administered per os, the gastric secretion having previously been neutralized with a solution of carbonate of sodium. In this case also the serum immunised guinea-pigs against Haffkine's *virus fort*. Unfortunately, we ommitted to test the immunising power of our own sera before the auto-inoculations. Klemperer has shown that the serum of some normal individuals has a weak immunising action. It is, however, very slight compared with that of the serum after treatment. Now in our case the immunising power was well marked, since 0.25 c.c. readily immunised guinea-pigs against large doses of Haffkine's *virus fort*. The serum of normal guinea-pigs, so far as our own experience goes, has no immunising action whatever.

12. It should also be mentioned that some of us, having been inoculated with repeated subcutaneous injections of virulent bouillon cultures, subsequently, when his serum possessed marked immunising properties showed only slight local reaction against a large dose of Haffkine's *virus fort* (half tube.) This, again, tends to show that the view of the distinct kinds of poisons should not be taken too narrow.

The above-mentioned serum experiments are possibly of some importance if Klemperer's law of the specificity of immunising serum holds good for all cases. The Klemperers insist on the truth of this law, and Behring agrees with them. According to this law the serum of an animal immunized by inoculations with the bacillus prodigiosus would immunize against this bacillus only, and not against any other infection; and similarly the serum of an animal immunized against "cholera" should not immunize against an infection with the bacillus prodigiosus. This question has also been touched upon; it will, however, require further careful and critical examination, because fallacies may easily be introduced by reason of the fact that the sera also of naturally immune animals have more or less marked immunizing properties.

We have found in accordance with Klemperer's law, that the serum of one of us treated by Haffkine's method will not protect guinea-pigs against intraperitoneal injections of "prodigiosus and pyocyaneus agar emulsions." So far too few experiments have been performed, but if our results be confirmed and Klemperer's experiments with the serum of cholera patients taken into consideration, it would bring us a step nearer the elucidation of the etiology of Asiatic cholera. Judging from Klein's theory of the intracellular poison and from its unequivocal results, we might have expected that the serum obtained from a person treated by Haffkine's method would protect animals against intraperitoneal injections of both "prodigiosus and pyocyaneus agar emulsions," but it was found that such serum will protect against any form of intraperitoneal injection of cholera bacilli only.

Without laying undue stress on the experiments just mentioned, we are led to the following conclusions after a survey of our own observations and those of others. As far as the cholera bacillus is concerned, (1) any one mode of immunisation will protect an animal against an infection by any other form of inoculation used; (2) the serum of an animal immunised by any one method also protects guinea-pigs against an infection by any one of the various forms of inoculation mentioned; (3) the distinction between an "intracellular" and a "metabolic" poision in their relation to artificial immunity must not be made too narrow.

We do not deny that an actual distinction between the metabolic and the protoplasmic poisons exists. Buchner's "proteins" apparently are what Klein calls the intracellular poison, and it is well known, from the researches of Buchner, Romer, and others, that the "proteins" produce reactions often different from those produced by the bacilli and their metabolic substances. Here, also, we must not be too exclusive. Whether Koch's tuberculin belongs to the proteins, as Buchner asserts, seems somewhat doubtful after the careful chemical studies of Hunter, but, on the other

hand, it is almost certain that it does not contain the specific toxin, at least not in a potent form. Now Vissman has shown that after injection dead tubercle bacilli scraped off agar agar into the ear vein of rabbits typical tubercles appear in the lungs and liver, which however, show no inclination towards caseation, but rather towards cicatrisation. Unfortunately, Vissmann has omitted to investigate the influence of such intravenous injections on immunity. If, however, as Klein and Buchner assume, tuberculin be the intracellular poison, then Kitasato has shown that by inoculations with this poison it is impossible to protect guinea-pigs against a tuberculous infection —a result which confirms our own conclusion that the "intracellular" poison against the bacillus and its specific toxin. —*Br. Med. Jour.*

## IMPORTANT EXPERIMENTS TOWARD MAINTAINING PURITY OF THE MILK SUPPLY.

Though each hot season brings out the truth of the assertion that contaminated milk is responsible for much infant mortality, yet the public is but slowly moved from its attude of indifference. Milk is one of the great foods, more important perhaps than any other, and is our main dependence in most cases of sickness and among the majority of children. The New Jersey commission, who, under the leadership of Dr. Coit, have given much time and thought to the investigation of the milk question, are convinced that a full supply of pure milk, if obtainable, would reduce the number of child deaths in summer one-half. The charitable experiment now being conducted by Mr. Nathan Straus at the foot of East 3d street, and which aims to supply sterilized milk to the poor, is worthy of praise of itself, and as calling public attention to the need of good milk.

Yet prevention is better than cure, and a supply of milk known to be pure would be better than a supply of milk treated to pasteurization for the killing of disease germs. Of course such processes as sterilization are a vast improvement upon the use of an impure article; but it is a question whether our real relief should not be sought in the direction of keeping the original purity of the milk intact rather than in destroying the bacilli after these have taken possession, since the process also takes from the milk something of its value as food. The important inquiry is whether this orginal purity can be maintained; and it is upon this point that the experiments of the New Jersey commission have much interest. No bacilli have ever been found in milk as it comes from the cow; yet in a single drop kept warm for two hours, 2,500 germs were found. That is to say, Nature will furnish the food absolutely pure when taken from healthy animals under proper feeding; it remains for the wit of man to keep it so. This is clearly a difficult thing to do. The hands of the milker, the udders of the cows, the hay and straw of the barn, the nuisances of the stable, may develop the dreaded germs. Just because milk is so important and composite a food, it the more readily becomes the carrier of disease. The theory of Henry L. Coit, M.D., adopted by the New Jersey commission, is that the problem must be solved by the application of medical, chemical, and agricultural expert knowledge to the production of milk on the farm and its transportation to the consumer. Experiments on these lines are now being conducted at a model farm near Caldwell, N. J. If it can be shown by these rigid experiments that milk which shall be free from germs can be obtained and delivered pure to infants and invalids, the way will be open for a practical reform. Boards of Health and the medical profession generally will watch the results with great interest and hope. The investigation is being conducted by a committee who deserve the confidence of the public as disinterested men (they receive no compensation), and as scientists whose opinions can be relied upon.

One thing we must not shut our eyes to. Pure milk, like any other good thing of importance, will, when obtainable cost money and time. Dr. Coit says that the present laws of New Jersey are sufficient in our present state of knowledge, if they

were but enforced. Enforced they will not be until public opinion is aroused to the importance of a supply of pure milk. Moreover, the process of obtaining milk under stringent regulations is more costly than the old slip-shod methods, and that extra cost must be paid by somebody. It is believed that this milk, certified to be germ-free and delivered in sealed bottles, can be sold for 12 cents per quart, though this is not yet certain. In Mr. Straus's charity, this extra cost is borne by the originator, the sterilized milk being sold at a little below first cost. If the State, for the protection of the people, should insist upon the rigid regulations which the Caldwell experiments may prove sufficient for purity, the result would be a general rise in price. At present the milk farmers of New York and New Jersey barely cover expenses in the low price which they are obliged by the competition with each other to take. They cannot feed better fodder to their cows or take more precautions against germs or uncleanness, unless they receive a cent or two more per quart.

In spite of this obstacle of increased cost, which must be settled in some way in the future, the first question to be solved is whether purity in our supply can be obtained and kept by any means. It is this question which the New Jersey commission, to their credit, are attempting to answer. After we know the solution, we shall be in a position to consider whether the State should not undertake to secure pure milk through the enforcement of existing laws under a competent comission, and whether the several commonwealths which furnish New York City with milk cannot agree upon the precautions to be insisted upon.—*New York Evening Post.*

## LEAVING CHILDREN TO THE CARE OF NURSES.

There is no duty of the mother so important, so sacred, as that of personally caring for her children, especially when they are very young. Duties to society, to education, to philanthropy, should all be secondary to this home duty.

When excuse can be offered for the woman who hires a nurse for her children and then gives up her time to so-called duties and pleasures which call her outside her home and away from the supervision of the nursery? It is not easily possible to secure for money, however liberally one may be able and willing to spend it, a person who will equal in refinement and education the child's own mother.

The care of children has been regarded as one of the lower occupations, and few educated girls will take the position of a nurse. Yet the brain and the thought-power of a child develop far more rapidly during the first two years of life than at any later period, and the child's disposition may be easily spoiled by injudicious handling. The difference between a fretful, cross child, making himself a nuisance to all around, and a sweet-tempered, laughing baby, is largely a matter of regularity and careful management. The impressions received, the language spoken, and the directions taken by the child's mind, are those of the persons with whom he comes most in contact. It is for this reason that French and German nurses are often sought, that the child may easily and naturally learn a foreign language. One hour with the mother will not counteract the effect of twenty-three hours with the nurse. Even granting that the care of an intelligent nurse over the physical wants of a child is of more value than that of the mother (which I do not believe), the direction of mind is far better taken charge of by the mother. This is not advocating a precocious education for the baby, but simply that the budding mind may have the best atmosphere to unfold in.

Let me give a few examples of the false impressions that the little ones often receive from their nurses. Many children live in constant terror of the "bugaboo" who catches naughty ones in the dark, or the man under the bed who will come out after them if they are left alone. Or they are taught to fear mice, spiders, worms and other harmless lower animals. This fear is never natural to children, but is taught them at so early an age that

they seem to have been born with it. A little child who sees a worm for the first time feels only interest and curiosity about it. He laughs, and wants to put his finger on it, to see how it feels and what it will do. Some ignorant person says, "the worm is nasty" or the worm will bite you"—and the child ever afterward fears that he may be bitten or poisoned by a creature that has no weapons against the human race, and whose habits are intensely interesting to many older as well as younger people. There is nothing more ridiculous than to see a girl scream and run away from a tiny spider. I know a lady who was laid up three weeks with a sprained ankle, the result of her frantic attempts to escape from a little mouse, who was doubtless more frightened than she. Yet I cannot remember the time when I had the slightest fear of any of these creatures. My mother taught me that they were harmless and interesting. Teach a baby under two years this fearlessness, and his mind will never be influenced against his early teachings.

Little children are naturally cruel from ignorance, and need a gentle mind to teach them that an insect or a kitten can feel pain as well as they. The girl, at six years old, who drags her kitten around the yard by a string tied round its neck, began with a nurse who did not teach her to care for and protect all beings weaker than herself.

Can we trust the nurse to guide and develop the early sense of right and wrong? Too often she comes from a family or a race in which these distinctions are far from clear in the minds of the elders. The child soon learns that nurse does not always tell the truth, that her word cannot be depended upon, and he naturally imitates her in this respect. We see little children pushing one another away from the best place, seizing the best piece of cake or the largest orange. It is but natural to the human mind. But this little seed grows into the great tree of selfishness and carelessness of the interests of others, of which we see so much in adults. Some children scream and howl whenever their wills are crossed in any way. A firm hand to break this habit means comfort and peace for the family in the future. These lessons of fearlessness, of unselfishness, of kindness and of self-control cannot be learned too early. The child who lacks these lessons develops into an excitable, high-strung, nervous being, a curse to himself and a constant anxiety to his parents.

Let us turn to the physical side of the baby's nature. If it were the custom to train young women to the care of well children, as it is to train them in the care of the sick, the nurse might be trusted with their physical welfare. But, unfortunately, our nurses are trained by experience only. All that is necessary is for a young woman to decide that she likes the care of children, and to present herself before the public in that light, to have her received, into some unsuspecting person's family and given the care of young children. She is probably ignorant of the rules of hygiene, of the needs of fresh air, and the ways of ventilating a room without a draft, of the proper temperature at which to keep her nursery, and the best ways of feeding children. She has seen her small brothers and sisters sit up all hours of the night, eat anything they can lay their hands on, and at any time they see fit to want food, and tumble about the floor as they like. These plans tried on her new charges soon bring about indigestion, bronchitis or irregular habits of sleeping. The results are but natural. In the absence of her mistress, she corrects her little charges at will; they learn to fear a blow, or to scream for whatever they want. The foundations are laid of ill-health and an excitable, unstable, nervous condition, which has much to do with the prevalence of nervous diseases in later years.

Am I depicting an extreme case? Then modify it for yourselves, and fill in the picture with other details. Let us take an "experienced" nurse. Can you safely trust her discretion in the matter of taking the children out in all weather and to all places? I know of a nurse who took two children, two and a half and five years old, to her home, where her father lay in bed, sick with smallpox. It was only by the description by the older child of "a man with sores all over his face" that the horrified mother learned where her children had been. The nurse had been so used to the presence of smallpox in a southern city that she knew no better. Many of the nurses whom I see on the

street are attending far more to gossip about their own affairs than to the welfare of their charges. If we fear to entrust our valuable bric-a-brac to the care of servants, how much more precious are these troublesome little comforts ?

Then watch over your nurse in season and out of season; study hygiene and diet; find a physician not too busy to talk over these subjects with you, and let him teach you how to keep your children well, instead of coming to them only when they are sick; and never let your nurse think she knows more than you do about the care of children. Spend as much time as you can possibly arrange with the children, and leave some of the cares of society and of charity to the women who have no "little darlings." A physician's wife said to me the other day, "I fear I shall not have time to come often to the club, as I am one of the mothers who are old-fashioned enough to take care of their own little girls." I went away, thinking what a sensible mother she was. Above all, teach your children to love you most of all, and not to cling to the nurse in preference to you. This will take time, but in it lies the hope of making them healthy, hearty and pure-minded.—*Mother's Nursery Guide.*

## ASIATIC CHOLERA IN ENGLAND.

The official notifications made during the past week prove beyond a doubt that our first line of defense has been forced, and that cases of Asiatic cholera have occurred in Hull and in Grimsby, not among ships' crews, but among permanent residents. The first recognized case was of a boy in Hull, on whom an inquest was held on August 25th. The inquiry was adjourned, in order that a bacteriological examination might be made. The material was transmitted to Dr. Klein, into whose custody it came on August 28th. Cultivations were immediately made, and on the following morning, August 29th, the sanitary authority in Hull was informed by telegraph that the case was undoubtedly one of Asiatic cholera. At the same time the information was transmitted to the Local Government Board, who at once despatched Dr. Thompson to Hull. As suspicious cases had occurred in Grimsby, where diarrhœa had been prevalent severely for several weeks, Dr. Reece was directed to proceed to that port. On August 30th a woman died with typical symptoms of cholera; a *post-mortem* examination was made, and Dr. Reece returned to London with a part of the ileum and some typical rice-water stool from this case. Cultures made from these specimens gave, after the usual intervals of about twelve hours, typical growths of the vibrio of Asiatic cholera, and on August 31st a telegram was despatched to Grimsby to this effect. On the following day, September 1st, similar materials were received from a second case which had been subjected to *post-mortem* examination on that day. The cultivation test again gave unmistakable evidence of Asiatic cholera, and the Grimsby authorities were so advised on September 2nd. Meanwhile a woman who lived in the same street in Hull as the boy upon whom the inquest was held on August 25th had been taken ill, and died. A *post-mortem* examination was made on the same day; the cultivations again gave unmistakable evidence of Asiatic cholera. This case gave rise to a third, the woman's daughter, who, on receipt of the news of her mother's illness, went to nurse her, was taken ill within twenty-four hours, and died with symptoms of Asiatic cholera.

Since then other cases have occurred in Hull and Grimsby, which have presented symptoms pointing to Asiatic cholera, although the diagnosis has not been confirmed by bacteriological examination. Elaborate precautions are now being taken in both of these ports, but it cannot be denied that the position remains serious. The Mayor of Grimsby has addressed a letter complaining that exaggerated statements have appeared in the press, and that, "whilst Grimsby is sparing no expense or trouble in adopting the most stringent measures to prevent the introduction of cholera into this country, it is being ungenerously and cruelly treated in return."

It is inevitable, however, that considerable alarm should be felt throughout the country, although we are glad to recognize that there are no signs of panic. At the same time we learn with some surprise that the railway excursion traffic to Cleethorpes, which is a suburb of Grimsby, has not been stopped, although it seems to be made a matter of complaint that it has been perceptibly affected, the number of excursionists being several hundreds below the avarage.

It is astonishing to learn that the efforts of the Rotherham Corporation to induce the Manchester, Sheffield, and Lincolnshire Railway to abandon a special excursion train to carry people from Grimbsy to Rotherham, to attend a football match, have been unsuccesful. The reason alleged is that there is no serious epidemic at Grimsby. The infection of Asiatic cholera is present in Grimsby, and Asiatic cholera, whatever the dimensions of the epidemic may be, is always serious.

That the continuance of excursion traffic may facilitate the dissemination of the disease is shown by the history of the case of Asiatic cholera which has occurred at Rotherham. The patient was a miner, who we learn, visited Grimsby on September 4th; he was taken ill on September 5th, and died the same day. Bacteriological examination proved that he had been suffering from Asiatic cholera.

Without wishing to bear hardly upon the sanitary authorities of Hull and Grimsby—brought face to face with a serious emergency the significance of which there may have some natural indisposition to recognize—we cannot help feeling that they would have been well advised to have had recourse at an earlier date to the bacteriological method of diagnosis.

Our Special Commissioner, who has visited Grimsby, furnishes us to day with facts which afford grounds for at least a strong suspicion that some of the cases of "cholera" and "diarrhœa" which occurred during the third week in August may have been really due to Asiatic cholera. Since August 20th 20 deaths have occurred in Grimsby from acute forms of diarrhœa, of which 18 have been returned "cholera" or "choleraic diarrhœa." The mortality, as our Commissioner points out, was high, and might well have aroused suspicion. The precautionary measures now in force are admirable, but it is possible that, had a bacteriological examination been made a week earlier, they might have been then enforced with the effect of saving life and protecting the trade of the port of Grimsby from the serious injury which it is inevitable it must now suffer.

In the *British Medical Journal* of July 26th was published an article on the examination of cholera discharges, which explained fully the methods now in use in bacteriological laboratories, and we mentioned then the names of various laboratories in this country in which bacteriological work is carried on and in any one of which the necessary examination would, we have no doubt, be promptly made. It may be well to add that the best material to forward is either some of the rice-water stool, or, if the case has terminated fatally, a portion of the lower ilium about eight or twelve inches in length. If a specimen of the stool is sent it should be put in a glass stoppered bottle, previously washed out with spirit, and the stopper tied down and sealed. If a piece of the ileum be sent it should be tied above and below and placed in a wide-mouthed glass stoppered bottle, previously washed out with alcohol. In neither case should any preservative or other fluid be added to the specimen contained in the bottle. The bottle should be thickly wrapped in cotton wool and packed in a tin box. If no specimen of the stool or the intestine can be obtained a portion of a sheet soiled by the discharges should be cut out, folded, wrapped in guttapercha tissue enveloped in cotton wool, and packed in a tin box.—*Br. Med. Jour.*

METRICAL EQUIVALENTS. The metric nomenclature is coming into such common use, especially in scientific articles, that the following formulas will be found valuable:

WEIGHT EQUIVALENTS.

| | |
|---|---|
| To convert grains into grammes multiply by | 0.065 |
| To convert grammes into grains multiply | 15.5 |
| To convert drachms into grammes multiply by | 3.9 |
| To convert ounces (avoir.) into grammes multiply by | 28.4 |
| To convert pounds (avoir.) into grammes multiply by | 453.6 |

MEASURE EQUIVALENTS.

| | |
|---|---|
| To convert cubic centimeters into grains multiply by | 15.5 |
| To convert cubic centimeters into drachms multiply by | 0.26 |
| To convert cubic centimeters into ounces (avoir.) multiply by | 0.036 |
| To convert pints into cubic centimeters multiply by | 473. |
| To convert liters into ounces (avoir.) multiply by | 35.3 |
| To convert gallons into liters multiply by | 3.8 |

—*Scientific American.*

# CURRENT LITERATURE REVIEWED.

THE ANNALS OF GYNECOLOGY FOR SEPTEMBER.

**The Operative Treatment of Backward Displacements of the Uterus**

is the title of a paper contributed by Dr. Ernest W. Cushing. After reviewing the various operations proposed for the relief of the condition, the author presents the following conclusions:

1. That many cases of retroflexion, and most cases of retroversion, if uncomplicated, cause little serious disturbance, and require no operative treatment.

2. That severe retroflexion in the virgin, when giving rise to symptoms sufficiently severe to call for treatment, is best relieved by operation.

3. That cases of retroversion which cannot be made comfortable by simple measures, such as the use of a pessary, are usually obdurate, on account of some complication which requires operation.

4. That of the operations designed for the cure of retro-displacements, the only ones worth considering are the Alexander-Adams operation, the various methods of intra-abdominal shortening of the round ligaments, and ventro-fixation.

5. That there is a legitimate and useful field for Alexander's operation, subject to the following limitations: The uterus must be free, the diagnosis must be exact, the anatomical conditions must be favorable.

6. That when these conditions are not present it is better to make a median abdominal incision and act according to circumstances.

7. That after opening the abdomen, if no complications are present, the uterus may best be secured in ante-position by shortening the round ligaments internally, and by placing at each cornu of the uterus one suture which passes through the abdominal wall.

8. That the latter operation may properly be performed instead of that of Alexander if the surgeon prefers it, as it is equally safe and more reliable on the average.

Dr. C. D. Hurt contributes an article on

**The Etiology of Puerperal Eclampsia; Its Treatment.**

After reviewing the various theories as to the causation of the convulsions the author says, in regard to treatment: If the increased sensibility is from an over-supply of nerve-force stored away for the woman in parturition, then veratrum and chloral are indicated. If a plethoric condition, the veratrum and venesection. If a truly anæmic and impoverished condition of the blood, then morphia and aromatic spirits of ammonia, with cautious use of veratrum. To secure prompt and decided relief when treating eclampsia, whether uremia is or is not present, unless the patient is very anæmic and with a broken down constitution, the author would, if she is of a full habit, draw twelve to twenty ounces of blood, then use hypodermically ten to fifteen drops of Norwood's tincture of viratrum viride; then order a quart of warm water thrown into the rectum. If the convulsions are post-partum he would first use the viratrum and warm enema, and see that the bladder was well emptied. The author states that he has resorted to chloral and chloroform and would by no means ignore these. He dislikes the use of morphia because of its tendency to check the secretions. Apomorphia he believes to be valuable in many cases but he has had but little experience with it.

Dr. Herman L. Collyer discusses the

**Treatment of Vaginitis by Peroxide of Hydrogen.**

The author states that he has been able to cure his cases more speedily by its use than any other means that he is aware of. It is his custon in the treatment of a case of vaginitis (purulent), first to wash the parts with warm creolin water in the strength of half a drachm to the pint, getting rid of all the secretion possible; then through a glass or rubber cylindrical speculum to thoroughly wash out the vagina. He uses peroxide of hydrogen (medical) plentifully, either full strength or diluted with luke warm water, and rubs the surface with a pledget of cotton, withdrawing the speculum at the same time (but not allowing it to come out) so as to allow the peroxide to get deep into the crpyts, destroying the pyogenic membrane and the gonococci, if any have imbedded themselves in the epithelium: he treats the vagina throughout in this manner, and also the vulva, especially in the folds of the labia and the orifices of the Bartholin ducts. Having destroyed every vestage of the pus with the peroxide of hydrogen, he pours into the speculum about an ounce of a solution of nitrate of silver, half a drachm to the ounce, and coats the denuded membrane throughout, inserting a strip of iodoform or aristol gauze to keep the parts separated, swabbing the external parts with the same solution, fifteen grains to the ounce. This process is repeated every second or fourth day, as the case demands. The patient is instructed to remove the gauze on the following day and to use, in acute attacks, a cool, weak solution of the lotion plumbi et opii or a solution of muriate of ammonia two or three times a day. When the symptoms become milder, the use of astringents is necessary. In specific vaginitis the endometrium and the urethra have often become effected, and these cavities are treated in the same manner, of course observing the precautions necessary for each, in all cases securing free drainage.

Dr. J. A. Prince contributes a paper on "Prolapsus with Retro-deviations of the Uterus treated by Ventro-fixation." After reporting a number of cases the author concludes as the result of his experience that the operation is justifiable in many cases.

In the department of Pædiatry, Dr. Eugene Revilliod presents some "Clinical Notes on Nephritis as met with in Children."

In summing up he says that nephritis is often a primary disease in childhood; the cause may often be found in the influence of cold, but often there is to be found no circumstances capable of explaining its origin. The most frequent form, from a clinical point of view, is the acute; from an anatomatical point of view it is the mixed. Albuminuria is an almost constant symptom. The quantity of albumin is most variable. It may be very abundant in serious cases. Slight nephritis may also give a large quantity of albumin in the beginning, but the quantity rapidly decreases. Anasarca is a less constant symptom than albuminuria, and collections in the serous cavities are rare. The complications that he observed could, in about all the cases, be attributed to the initial disease. This was the case especially with pleuro-pneumonia, several cases of endo-carditis, one of rheumatism, and two of peritonitis.

Dr. Henry N. Cattell contributes a paper entitled "Some Special Points on the Performance of Autopsies on the New-born."

The other contributions in this issue are: "A paper on Extra-uterine Pregnancy" by Dr. A. H. Cordier. "A Useful Addition to the Edebohl's Operating Table" by Dr. I. S. Stone. "The Treatment of the Retroverted Uterus, with special reference to the Value of Massage and the Author's Application of the Uterine Respiratory Movement," by Dr. D. H. Williams, and "A Favorable Termination of a much neglected case of Suppuration of the Appendix Vermiformis," by Dr. Z. H. Evans.

---

THE UNIVERSITY MEDICAL MAGAZINE

for September. Dr. John B. Deaver furnishes an interesting paper on

**The Treatment of Appendicitis.**

He proposes that the term intra-peritoneal inflammation should include all cases of inflammation in the right iliac fossa having their origin within the peritoneum and associated with lesions of the cecum or the appendix, for the following reasons: (1) He believes it impossible to differentiate between appendicitis, typhilitis and peri-typhlitis; (2) He believes the terms typhlitis and perityphlitis to be misleading, and as long as it is taught that they are distinct affections, independent of trouble with the appendix, just so long will the physician be misled as to the true character of inflammation in this region. He asserts that all inflammations of the right iliac fossa, excluding inflammatory affections of the overlying abdominal muscles, have their starting point in the appendix. All cases of appendicitis are divisible into five classes: catarrhal, obstructive (due to the presence of a foreign body, as a fecal concretion, an enterolith, a stricture, etc.), perforative, tubercular and relapsing.

The treatment which offers the best opportunity for permanent relief is that of immedate removal of the offending appendix as soon as the diagnosis is established. His reason for adopting such a radical course has been forced upon him by the large number of cases he has seen perish when well-directed medical means had failed to afford relief, many of the patients being beyond surgical aid. While he has seen cases of acute appendicitis recover without operation, this has not been the rule, but the exception. Furthermore, being unable to subsequently observe the cases supposed to have recovered without operation, it is impossible to estimate how many of these suffered from relapses. If reliable statistics were available upon this point an arbitrary rule could be made.

The points he observes in making the incision for the removal of the appendix in acute cases where there is present a mass, be it pus or exudate, are the following: When the loin is rendered prominent by the mass or is the seat of edema, he takes it as an indication that the appendix holds a post-cecal or an external antero-lateral position or that it comes off from the apex of the cecum, and he carries the incision parallel with and a short distance above the outer third of Poupart's ligament, prolonging it outward if necessary. When the mass presents itself well to the inner side of the anterior superior spine of the ilium, he carries the incision through the semi-lunar line, rather through the rectus muscle immediately to the inner side of the semi-lunar line. The wound, when carried through the muscle, heals more solidly and, therefore, there is less likelihood of the development of a ventral hernia than when made through the semi-lunar line.

In concluding the paper he cautions against operation, when time is not an element, until the patient has been thoroughly prepared, that is, by rest in bed for two, three or more days, a limited but nutritious diet, and, most important of all, the free evacuation of the bowels. In acute attacks of appendicitis he always feels that the operation is certain to be a success if the patient has had two or more free evacuations during the day of operation; while, on the other hand, in acute cases when the bowels have been kept locked up with opium, he never feels sure of the result.

Dr. Joseph McFarland discusses the question

**Are Coccidia Found in Cancer?**

After carefully reviewing the opinions of the observers and workers in this subject, he deduces that from all the evidence, we are obliged to conclude that the bodies found in cancer cells and described as parasites, are not of such nature, but are phenomena occurring from disease and degeneration of the cells, and have nothing to do with the etiology of cancer. While he does not deny the possibility of the presence of animal parasites as well as bacteria in the ulcerated and degenerated portions of epithelial tumors, he is obliged to regard even this as unproven.

Dr. John C. Heisler contributes a paper on

**Cystitis in the Female.**

In almost every case, certainly in the majority, careful inquiry will disclose some er-

ror in diet or defect in digestion. Prominent among the former, is the habit of partaking freely, almost inordinately it may be, of acid fruits and of highly stimulating condiments. The sparing use of drinking water may be, at least, a powerful predisposing cause of bladder irritation, and if the patient is a heavy feeder, or is addicted to the free use of acids and condiments, will certainly very greatly aid in producing the disease. Gastric digestion, intestinal digestion and bowel evacuations having each received the physician's attention, he may next proceed to a physical examination of the pelvic organs. Whether there is flexion, version, descent, or other morbid condition of the uterus, should be noted, as well as the state of the ovaries. Tenderness of the urethra should be inquired for, by passing the finger along the roof of the vagina with slight pressure. It should be borne in mind that anything keeping up pelvic congestion will interfere with the cure of the cystitis. That microscopical and chemical examination of the urine should always be made, goes without saying.

The chief indications for treatment are: (1) To remove any discoverable source or sources of irritation; (2) to render the urine bland; (3) to relieve pelvic congestion if it exist; (4) to treat locally the inflamed mucous membrane; (5) to improve the patient's general health; (6) to secure rest for the patient by keeping her in bed, at least in all acute cases.

The remaining paper is by Dr. James Wallace on "Glaucoma." In the clinical department is the report, by Dr. Francis Lieber, of the fractures treated in the dispensary of the Episcopal Hospital during the service of Drs. Davis and Van Pelt.

# PERISCOPE.

## MEDICINE

### Embolism of the Popliteal Artery Following Diphtheria.

Rooney (*Occidental Medical Times*, April, 1893) reports a case of diphtheria which was followed by embolism of the left popliteal artery. Gangrene resulted, the line of demarcation extending obliquely from the patella in front downwards and backwards to the top of the belly of the gastrocnemius. Amputation through the thigh at the junction of the lower and middle thirds was performed, and the patient recovered.

### Epilepsy.

Miller (*Edinburgh Medical Journal*, July, 1893) reports a case of epilepsy which was cured by the removal of a contraction of the slips of the palmar fascia going to the ring and little fingers of the right hand, and also the slitting up of a contracted prepuce. The fits used to commence by the fingers of the right hand becoming flexed, with the thumb over them; the arm then became flexed until the hand touched the shoulder. The rigidity extended to the right leg, and then became general, the patient losing consciousness. Some months after the operation the patient reported himself quite well.

### Bathing After Excessive Exercise.

The popular notion of the injurious effect of a cold bath taken by one who is overheated from exercise, must possess—as all such ideas have—some basis in experience; and yet it is falsified by the experiences of athletes from the days of the Greeks and Romans even until now, who find in this procedure a refreshing and stimulating tonic after the exertion they have recently undergone. And, physiologically speaking, a cold plunge or douche taken immediately after the physical effort, when the skin is acting freely and there is a sense of heat throughout the body, is as rational as in the experience of the athlete it is beneficial. It is paralleled by the tonic effect produced by the cold plunge when the skin is actively secreting after a Turkish bath, and finds its rationale doubtless in the stimulation of the nervous system, in the increase of internal circulation, and also in the renewal of activity to the cutaneous circulation after the momentary contraction of blood vessels due to the cold. The popular belief, doubtless, rests on the injurious effects which may be induced by the bath in one who does not resort to it immediately, but allows time for the effects of fatigue to show themselves on the muscles and nerves and for the surface of the body to get cool. Taken then the bath is more likely to depress than to stimulate, there is less power of reaction and greater liability to internal inflammations. At such a time a warm bath rather than a cold one is more suitable and more safe. It has been suggested, however, that the practice of indulging in a bath after violent exercise may initiate renal disease. Of this there is no evidence. The transitory albuminuria observed after prolonged cold baths may indicate the disturbance in the renal circulation which ensues upon them, but these cases are in a different category from those to which we are now alluding, nor are we aware of any facts to prove that even in them Bright's disease has been developed in consequence of the transient departure from the normal. Lastly, it must be remembered that those indulging in athletic exercises of all kinds are presumably sound in heart as well as limb, and that such persons may take with impunity, and, indeed, with benefit, measures which would be distinctly harmful to the weakly.—*Lancet.*

### Diabetes and Cirrhosis of the Liver.

Palma (*Ber. klin. Woch.*,) describes two such cases from cases from the clinic of v. Jaksch. (1) A man, aged 78, had suffered from increasing weakness for eighteen weeks. The skin was of a brownish color. There was considerable hepatic and splenic enlargement. The urine contained much grape sugar, but no bile pigment. The case is described as one of hypertrophic passing into atrophic cirrhosis. (2) A man, aged 43, began with slight jaundice four months previously. Two months later the abdomen began to swell, and, fourteen days ago, the legs. Ascites was present. The liver and spleen could not be felt. The urine contained grape sugar and occasionally, acetone, as well as bile pigment. A month later he died. The liver was found to be cirrhotic, the kidneys enlarged, and the pancreas healthy. The liver only contained a small quantity of glycogen. In such cases either the sugar-forming function of the liver is increased, and too much sugar gets into the blood, or the liver is not in a position to convert the sugar brought to it into glycogen. The question of alimentary glycosuria must also be considered. Here the limit for the assimilation of carbohydrates is diminished, and a permanent glycosuria may result. The effect of alcohol in this respect has been insisted on. The author draws attention to the pigmentation seen in his case, and refers to the condition of "bronzed diabetes." He concludes by pointing out (1) that the cœxistence of these two diseases is very rare; (2) that the liver disease cannot as yet be looked upon as the cause of the diabetes, and that the latter may be a chance complication; and (3) that the name bronzed diabetes should not be used, as pigment may be absent from the internal organs in such cases, and in ordinary cirrhosis without diabetes this accumulation of pigment may also be present.—*Br. Med. Jour.*

---

### Relation between the Alkalinity of the Blood and Intestinal Absorption.

Castellino and Cavazzani (*Gaz. degli Ospitali,*) have sought to ascertain whether, and if so how, the process of absorption from the intestine is modified in association with altered physical and chemical conditions of the blood; secondly, they have sought to establish how such changes of the blood influence in the human subject the general metabolism of the body. The study is not as yet complete, but the authors have ascertained the following facts: In distinctly alkaline serum, the reticulum of the hyaloplasm of leucocytes undergoes stimulation, which causes increased irritability and more active vital manifestations in the protoplasm. In liquids poor in alkali the protoplasm appears torpid and slow in its reactions, but in these cases contact with alkaline serum speedily evokes increased activity; Contact of faintly alkaline serum with leucocytes in a medium favorable to their activity depresses their movements, and accelerates the processes of degeneration. Serum which is but faintly alkaline nearly always produces transparency of the protoplasm, and throws out the nucleus. From the above facts, the authors argue, first, that alkalinization of the blood favors intestinal absorption; and, secondly, that as the passage of foods from the intestine through the lining mucous membrane is probably due in great measure to the activity of the cells lining the villi and to the leucocytes, alkalies would cause an increase in the rapidity of absorption by stimulating the activity of the protoplasm, and increasing its chimiotactic powers.

---

### Double Empyema.

Cassel (*Deut. Med. Woch.*) reports a case in a wasted child, aged four months, who was thought to have had an attack of influen a. On the left side there was well-marked bronchial breathing at the angle of the scapula behind, and from this point downwards on both sides the percussion note was impaired and the breath sounds ill-defined. In front there are no abnormal signs, and the apex beat was not displaced. The chest was opened on both sides in the sixth interspace, $\frac{3}{4}$ litre of pus being let out on the right, and $\frac{1}{3}$ litre on the left side. The immediate result was good. The improvement was not maintained, so that resection of rib was practiced. The child died later. Pleuritic adhesions were found everywhere except at the sites of the empyemata. A vomica was found in the left lung communicating with the pleural cavity. Many tuberculous foci were found scattered through the lungs. Double-sided pleurisy is not so very rare. The only treatment that could be practiced here was opening the chest. Tuberculosis of the lungs may, however, be a contra-indication. At this age the recognition of a tuberculous lesion in the lungs would necessarily be very difficult.

---

### Syphilitic Spinal Paralysis.

Kowalewsky (*Neurol. Centralbl.*) reviews the clinical features and differential diagnosis of the affection described under the above title by Erb and designated syphilitic transverse myelitis by Charcot. The disease is almost confined to males between 30 and 45 years of age; its development is slow; disturbance of the bladder function is often one of the earliest indications. Frequently, in addition to symptoms resembling spastic paraplegia, there are sensory disorders of diverse kinds, sometimes with trophic derangements. Spasticity of gait, however, is not always observed, and never is so marked as in lateral sclerosis; muscular rigidity and increase of deep reflexes also are less pronounced than in spastic paraplegia. Amongst 152 cases of syphilis of the central nervous system treated by the author during 1892 there were 38 affected with tabes and 21 with syphilitic spinal paralysis. In all the latter there was functional derangement of the bladder, mostly shown by inability to restrain detrusor action whenever the desire to

micturate arose. The rectal function was similarly deranged in many of the cases. Increased myotatic irritability was a constant condition. Great exaggeration of the "thermic reflex" in the lower limbs was found to be a characteristic peculiarlty of the disease; cold or heat applied to the lower extremities evoked strong convulsive contraction. The psycho-physical reaction time for tactile and painful stimuli was normal or slightly shortened—an opposite condition to that obtaining in tabes.—*Br. Med. Jr.*

### Large Doses of Digitalis in Croupous Pneumonia.

Mario Bellotti (*Gazz. degli Ospitali*) treats of the virtues of digitalis in croupous pneumonia, the present paper being a continuation of a similar one published a year ago. His conclusions from a large number of observations on cases in which Fraenkel's diplococcus has been detected are as follows: (1) All cases of fibrinous pneumonia, due to Fraenkel's bacillus, receive very great benefit from large doses of infusion of digitalis, always accompanied by milk diet, and occasionally by bleeding. (2) It is necessary to give the digitalis in very large doses, because in pneumonic conditions, both the gastric catarrh which is usually present, and the dimunition of HCl of the gastric juice reduce greatly the amount of the drug which actually passes into the portal circulation. (3) Some of the active principles of digitalis seem to exercise a special elective action on the pneumonia toxins, this action taking place chiefly in the liver.

### Artifical Delivery in Copenhagen.

Th. Hansen states that in Germany, after the introduction of antiseptics, accoucheurs seem to have been more disposed to resort to artificial delivery, the mortality being thereby increased. This is not the case in Denmark. Hansen has consulted the registers of the midwives of Copenhagen, who are compelled to register every delivery in their practice, and who attend all women in labor, and has compared the number of artificial deliveries, in that city from 1862 to 1869, with those made from 1888 to 1890. The following are his figures:—

| | *Deliveries.* | *Forceps.* | *Version.* |
|---|---|---|---|
| 1862–69 | 17,887 | 305 (1.71 per ct.) | 120 (0.67 per ct.) |
| | *Deliveries of Placenta.* | | *Artifioial Deliveries.* |
| | 132 (0.74 per ct.) | | 557 (3.10 per ct.) |
| | *Deliveries.* | *Forceps.* | *Version.* |
| 1888–90 | 16.639 | 275 (1.65 per ct.) | 70 (0.42 per ct.) |
| | *Deliveries of Placenta.* | | *Artificial Deliveries.* |
| | 115 (0.69 per ct.) | | 460 (2.77 per ct. |

—*Hospitals-tidende*, 1893, p. 476.

### Myositis Ossificans.

A case of myositis ossificans, in a young man of 20, is reported by Brennsohn. Many muscles were involved including those of the back, the boundaries of the axillæ, the deltoids, serratus magnus, biceps, brachialis anticus; neck muscles, abdominal muscles, and those of the thigh.—*Berliner klinische Wochenschrift*, November 14, 1892.

### Complete Reunion of Severed Fingers.

Finney sutured the ends of the ring and middle fingers in place seven hours after they had been cut off by a machine. Firm union took place within two weeks. When seen, at the end of three years, motion and sensation were complete. Antiseptics were avoided because they form a thin layer of coagulation-necrosis, which might interfere with union.—*Johns Hopkins Hospital Bulletin*, October. November, 1892.

## SURGERY.

### Operation for Umbilical Hernia on the Newborn Child.

Berger (*Nouvelles Arch. d'Obstet. et de Gynec.*) successfully operated on a female child thirty hours after birth, and exhibited it afterwards at a meeting of the Obstetrical and Gynecological Society of Paris. The infant was born strong, breathing well. The umbilical hernia was of the size of a small hen's egg, and covered by the membranes of the cord. There was a distinct neck or pedicle as thick as a man's forefinger, and made up of integument alone, which was united to the membranes by a deep groove. The lower part of the hernia was reducible, and the sac was there transparent. Coils of small intestine showed through it; they could all be pushed back into the abdomen. The upper part was irreducible, and in close relation with the vessels of the cord. After birth the hernia and abdomen were well washed and dressed with iodoform. On the next day the hernial sac was opened, and the small intestine reduced. The irreducible portion consisted of the cæcum, the appendix, and about one-third of the large intestine, all intimately adherent to the membranes of the cord. A layer of these membranes had to be detached and reduced, together with the bowel. This manœuvre could not be done until a free incision had been made along the median line, as in abdominal section. The sac was excised. The peritoneum, the aponeurosis, and the skin were separately sutured. The operation lasted an hour and a quarter. The sutures were removed on the tenth day; recovery was complete at the end of a fortnight. Gueniot, in the discussion on Berger's case, referred to Lindfors's invaluable monograph "On Umbilical Hernia," which appeared last January in Volkmann's *Vortrage*. He said that, as in adults, very minute particulars of each case of this operation in infants would be needed. Nothing differed so much as two umbilical herniæ. Other abdominal viscera besides the intestine may lie in the sac, inseparably adherent, and the abdominal cavity may, by congenital defect, be much too small to hold all the herniated structures.

## NEWS AND MISCELLANY.

### Gulling the Public.

A recent trial has again brought this subject into the newspapers, and has let some light into the inner working of so-called "cures" for consumption, and into the methods by which "cases" are worked up, the books and pamphlets "puffed" by even respectable newspapers.

The whole story is pitiably sad. At one time a respectable medical practitioner deviates from the path of rectitude, is guilty of "infamous conduct in a professional respect," and his name is removed from the Medical Register. A book is then published called "Prevention and Cure of Consumption." This book is just as valuable as all these kind of books are, and the medicines they recommend are not worth the paper they are wrapped up in. But there are plenty of interested people, including proprietors of newspapers, — especially religious newspapers,—ready themselves to puff such books or to introduce into their pages mendacious advertisements. Such books and medicines are not only useless, but they are dangerous. It was said by the defendant, who ought to know, seeing he had been "dispensing the medicine for 15 years," that the medicine contained "enough strychnine to kill 2,000 people in a year, also morphia and chloroform."

The presiding Judge—Mr. Justice Wright —showed more than usual common sense in medical matters, as will be seen from the following cross-examination:—

Upon taking his seat his Lordship inquired whether the plaintiff was in court, and counsel replying in the affirmative, required him to go into the witness-box. He then told plaintiff, Mr. Alabone, that he need not answer the questions unless he liked. There was, he said, a large number of what were called press notices, purporting to be reprinted from the *St. Stephen's Review*, the *Christian World*, the *Guardian*, the *Echo*, the *Observer*, the *John Bull*, the *Advertiser*, the *Whitehall*, and the *Court Journal*.

Refer to page 249 of the *Guardian*. Is that your own composition?—Not that I am aware.

What do you mean by that answer? Did you write it or not?—I did not. (Witness was understood to say that he might have read and corrected a proof.)

Were any of these opinions paid for as advertisements?—No, but advertisements were to be given on condition that a notice appeared. I read the proofs.

Do you mean to say that the *Guardian* made that kind of a bargain?—I cannot say. The *Echo* certainly did.

Do you mean to say that the arrangement was made by the *Guardian*, *Observer*, *Echo*, *&c.*, that they agreed to insert praises of your book if you would give them an advertisement?—I don't know about praises, but they gave notices of the book.

No payment was made to the *St. Stephen's Review*?—The only payment was a certain number of copies.

His Lordship questioned the witness as to whether payment had been made to any of the above papers, mentioning them *seriatim*, and the witness replied that no payment had been made. In like manner the plaintiff denied that any payment had been made for testimonials.

Questioned about lacnanthe, he said it came from New Zealand. He mentioned the names and addresses of the firms from whom he bought it, and wrote down a name and address of a person from whom he procured the root itself. In like manner he wrote down by the judge's direction the materials that entered into the composition of the lacnanthe recipe.

At the conclusion of his evidence his Lordship said: This is an action brought by plaintiff to restrain Mr. Morton from pirating certain medical testimonials, and from dishonestly making use of professional information obtained by the defendant whilst acting as confidential clerk of the plaintiff, and from representing that certain so-called opinions of the press relating to the plaintiff relate to the defendant. The plaintiff is a person who was once qualified to practice as a surgeon, but who has been struck off the register. He nevertheless continues to practice as a surgeon. He also prescribes, prepares, and sells drugs for non-surgical purposes, thereby subjecting himself to penalties under the Apothecaries' Act. The defendant is a person who never had any qualification, but who having learned the business from the plaintiff, is now following it as a rival on his own account, with the addition that he represents some of the plaintiff's pretences to be his own property. He admitted engaging with the plaintiff in what he acknowledged to be a criminal conspiracy to defeat the provisions of the Medical Acts, and he admitted —whatever his admission may be worth— having been a party to wholesale illegal supply of strychnine and other poisonous drugs. The plaintiff's book is designed to puff an alleged specific for consumption which it is not uncharitable to suppose inert, if not injurious. It is recommended by so-called opinions of the press, and by statements of cases of alleged cure, and by alleged testimonials from patients. The alleged opinions of the press have every appearance of being not independent opinions or real notices, but paid or arranged notices or advertisements. The alleged cases do not appear to correspond with the case books from which they are said to have been taken. The alleged testimonials are, no doubt, in some cases written by patients in good faith, but many of them have a highly suspicious character and are suggestive of concoction or purchase. In this connection his Lordship observed that there were circumstances which indicated that the suspicions roused by a perusal of the plaintiff's book were well-founded. The learned Judge proceeded: When taken with the other admitted facts in relation to the plaintiff's business they oblige me to think that the business may probably be a cruel and nefarious system of obtaining money by false pretences from persons who are induced to believe themselves

consumptive. If this is so the law will not lend its aid to protect a book published as part of such a scheme. No doubt the case is not at present carried beyond grave suspicion, but where ground for such suspicion exists I think the Court ought not to act blindfold. It was not for the interests of either party to assist Justice in reference to these considerations, and I am unable to reply upon or accept the evidence of either party except to a very limited extent. There will, therefore, be further inquiry by the official solicitor and Public Prosecutor to inquire of the newspapers whether these notices were paid for or in any way arranged Either party may, if so advised, put the case in the paper for judgment on July 3rd. In the meantime the books and papers will remain in my custody.—*Pop. Med. Month.*

## ARMY AND NAVY.

U. S. MARINE HOSPITAL SERVICE FOR THE SIX WEEKS ENDED SEPTEMBER 16, 1893.

Murray, R. D., Surgeon; to proceed to Pensacola, Florida, for temporary duty, August 10, 1893; to rejoin station, August 18, 1893; to proceed to Brunswick, Georgia, for temporary duty, September 14, 1893.

Bailhache, P. H., Surgeon; to assume charge of inspection of immigrants, August 14, 1893; detailed as chairman board for physical examination of keepers of Life Saving Stations, August 18, 1893; relieved from duty as Inspector of Immigrants, August 22, 1893; detailed as chairman board for physical examination of officers, Revenue Marine Service, September 12, 1893.

Purviance, George, Surgeon; to report at bureau for temporary duty, August 6 and 10, 1893; detailed as chairman board for physical examination of Surgeon John Vansant, August 28, 1893.

Vansant, John, Surgeon; ordered before board for physical examination, August 31, 1893.

Hutton, W. H. H., Surgeon; to report at Brunswick, August 10, 1893; to proceed to Cape Charles Quarantine as Inspector, August 12, 1893; to proceed to Brunswick, Georgia, for temporary duty, August 12, 1893; to rejoin station, Detroit, Michigan, September 10, 1893.

Hamilton, John B., Surgeon; granted leave of absence for four days, August 16, 1893; granted leave of absence for ten days, August 29, 1893.

Sawtelle, H. W., Surgeon; detailed as member board for physical examination Life Saving Station, August 18, 1893; detailed as member board for physical examination of Passed Assistant Surgeon, H. T. Goodwin, August 22, 1893; detailed as member board for physical examination officers Revenue Marine Service, September 12, 1893.

By direction of the Secretary of War, leave of absence for four months, on Surgeon's certificate of disability, is granted Lieutenant Colonel Francis L. Town, Deputy Surgeon General U. S. Army.

Austen, H. W., Surgeon, Detailed as recorder Board for physicial examination of Surgeon John Vansant August 28, 1893. To represent the Service at Meeting Pan-American Medical Congress, September 5, 1893.

Gassaway, J. M., Surgeon. To inspect local quarantine at Pascagonla, Miss., August 23, 1893.

Mead, F. W., Surgeon. To proceed to Chicago, Ill. for temporary duty August 9, 1893.

Carter, H. R., Surgeon. To proceed to Fernandina, Fla. to inspect quarantine, and return to Bureau, August 7,1893. To proceed to Pensacola, Fla., August 10, 1893. To proceed to Brunswick, Ga. for temporary duty, Augsut 12, 1893. To report at Bureau Aug. 31, 1893. To represent the service at Pan-American Medical Congress, September 5, 1893. To proceed to Philadelphia, Penna., and Reedy Island quarantine September 9, 1893. To proceed to Cape Charles quarantine and assume Command, September 11, 1893. To report at Bureau for temporary duty, September 13, 1893.

Wheeler, W. A., Surgeon. Detailed for duty at Camp Lou., August 14, 1893. To rejoin station August 22, 1893. Detailed as Recorder Board for physician examination P. A. Surgeon, H. T. Goodwin, August 22, 1893.

Carmichael, D. A., Pass-Asst. Surgeon Granted leave of absence for thirty days, August 16, 1893.

Peckham, C. T., Passed Asst. Surgeon, Granted leave of absence for twenty days, August 10, 1893.

Glennan, A. H., Passed Asst. Surgeon. To proceed to Reedy Island quarantine for temporary duty, August 30, 1893.

Magruder, G. M., Passed Asst. Surgeon. To proceed to Pensocola, Florida, as Inspector, August 10, 1893. To proceed to Brunswick, Ga., for temporary duty August 23, 1893. To proceed to Beaufort, S. C., as Inspector, September 9, 1893.

Kinyoun, J. J., Passed Asst. Surgeon, Detailed as Inspector New York quarantine, August 12, 1893. Detailed as member board for physical examination of P. A. Surg, H. T. Goodwin, August 26, 1893.

Goodwin, H. T., Passed Asst. Surgeon, Granted leave of absence for thirty days, August 10, 1893. To proceed to Louisville, Ky., for duty August 15, 1893. Ordered to appear for examination as to physical condition, August 22, 1893.

Varighan, G. T., Passed Asst. Surgeon. To represent service at meeting of Pan American Medical Congress, September 5, 1893.

Geddings, H. D., Passed Asst. Surgeon. To report at Bureau for temporary duty, September 13, 1893. To proceed to Brunswick, Ga. for temporary as Inspector, September 15, 1893.

Cofer, L. E., Asst. Surgeon. To proceed to Savanah, Ga. for duty, August 25, 1893.

Decker, C. E., Asst. Surgeon. To proceed to San Francisco quarantine for temporary duty, September 3, 1893.

Nydegger, J. A., Asst. Surgeon. To proceed to Jersey City, N. J. for temporary duty, September 2, 1893. To rejoin station, Sept. 9, 1893.

Oakley, J. H., Asst. Surgeon. To Proceed to Quebec, Canada, for duty August 26, 1893.

## WHY "MUMM" IS SO POPULAR WITH PHYSICIANS.

G. H. MUMM & CO.'S EXTRA DRY is recommended for its purity, its small amount of Alcohol, and its wholesomeness by such eminent physicians as:

**Dr. D. Hayes Agnew, Thos. G. Morton, Wm. H. Pancoast,** . . *PHILADELPHIA*
" **Fordyce Barker, Lewis A. Sayre, Wm. H. Thompson,** . *NEW YORK*
" **Alan P. Smith, H. P. C. Wilson,** . . . . . *BALTIMORE*
" **J. Mills Browne,** *Surgeon-General U. S. Navy;* **John B. Hamilton,** *Supervising Surgeon-General, Marine Hospital Service;* **Wm. A. Hammond, Nathan S. Lincoln,** . . . . . *WASHINGTON*
" **H. Byford, Chr. Fenger, R. Jackson, C. T. Parkes, E. Schmidt,** *CHICAGO*
" **A. C. Bernays, W. F. Kier, H. H. Mudd,** . . . . . *ST. LOUIS*
" **A. L. Carson, James T. Whittaker,** . . . . . *CINCINNATI*
" **Stanford E. C. Chaille, Joseph Jones, A. W. de Roaldes,** . *NEW ORLEANS*
" **C. B. Brigham, R. B. Cole, Levi C. Lane, J. Rosenstirn,** . . *SAN FRANCISCO*

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it, not only for its purity, but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M. D, *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

**NO OPENERS REQUIRED.** In using G. H. Mumm & Co.'s Extra Dry in sick rooms and families.

**CHAMPAGNE IMPORTATIONS.** Custom House statistics of 1892 show G. H. Mumm's Extra Dry to be 75,880 cases, being more than one fifth of the entire champagne importations and over 9,000 cases more than of any other brand. It is noted for its excellence, purity and natural dryness.

G. H. Mumm & Co.'s Extra Dry of the excellent 1889 vintage is attracting great attention for its natural dryness, purity and quality.

## ORIGINAL ARTICLES.

### BLOOD-LETTING AS A THERAPEUTIC AGENT IN THE TREATMENT OF DISEASES.*

J. S. DUKATE, M. D.

"*Stat magni nominis umbra.*" "It stands the shadow of a mighty name." There is a great diversity of opinion, and a tendency to reaction in regard to the utility of blood-letting. Some holding it to be unique, single in kind or excellence. To the old physician it is a souvenir of the past.

For nearly half a century I have been a close observer of its effects clinically, and I have always considered it, when judiciously employed, a *semper fidelis*—always faithful in its results, and it should be in the hands of every physician a *semper paratus*—always ready. But for years it has only been known as "the lost art." Why? Because times have changed and we must change with them.

But the great question that confronts us is, must we ignore all the learning and clinical experience of the past; must we say physicians of fifty years ago were all in error; that their knowledge of physiology, pathology and therapeutics was a heterogenious mass of crude notions and absurdity. Were all the eminent surgeons and physicians of the past deficient clinicians. They were eminent clinicians, and laid the foundations of medical science deep and permanent. They all advocated and used the lancet, and yet we of to-day say—"*dulce et decorum est-pro patria mori*"—and it is sweet and glorious that we old practitioners die to the past surrounded by such eminent lights as Hunter, the Coopers, the Bells, Abernethy, Brodie, Travers, Lawrence, Thompson, Eberle, Rush, Parrish, Dewees, and many more too tedious to mention, whose fight with disease and death was as successful as that of modern practice in all the varied departments of morbid action. It has been said that all these men and many more, turned their wards and private rooms into slaughter houses with the lancet, and killed more than they cured. Surgery is to-day just where John and Charles Bell left it fifty years ago, with only the Listerian mode of dressing wounds, and as applied in operations, which is a valuable addition to surgical therapeutics. The ligation of arteries, amputations and trephining are performed now just as they were fifty years ago, so far as the mechanical surgery is concerned, although I am free to admit that abdominal surgery has advanced quite rapidly and successfully.

A few years ago I heard it stated in a medical society, by a reputable physician now dead, that no physician of any note or standing in the profession would have the hardihood to stand up and advocate blood-letting either in the strictly inflammatory or nervous types of disease. Shortly afterward, this same physician was called in consultation in a case of parturient-convulsions and bled the patient freely and saved her life. Meeting him

*Read before the Pike County Medical Society, Ind.

afterward, I said to him, "How comes it, you resorted to venesection in this case, holding the views you do against the remedy?" He remarked, "Well, I looked upon it as the last resort." I remarked, "You should have looked upon it as the first remedy, the *sine qua non*, and everything else as simple adjuvant.

Before I enter clinically into the consideration of blood-letting, I wish to speak briefly of it as a means of diagnosis in some of those obscure cases, where doubt exists as between a neurosis and an inflammation. These cases are usually marked in their pathological significance and therapeutical remedium. When inflammatory blood is drawn, it coagulates more slowly than healthy blood; the clot is harder and smaller, and the quantity of serum is apparently greater. Then inflammatory blood never fails to exhibit the tough yellow fibrinous stratum known as the "buffy coat"—depressed in the center with elevated edges resembling somewhat Hunterian chancre, "cupped" as the old term expressed it. By the abstraction of a small quantity of blood where I have been perplexed and in doubt, I have had all doubt removed in forming a diagnosis as between an inflammation and a neurosis, and have been led into the right path in my therapeutics when I found the above conditions of the blood present. Of course, I discard the "buff" when dependent on strictly physiological laws, as plethora, gestation, active exercise, etc., but my argument has reference strictly to pathological conditions.

We will find the pathological conditions of the blood greater when the fibrous or the serous tissues and parenchyma of organs are the seat of either acute or subacute inflammation; and least, if not entirely wanting, in mucous and tegmentary tissue. To the eye alone, we may find all the local signs of inflammation from a subjective point, such as alteration of color and size, modification of sensation, increase of temperature with modification of the function of the part; I say, it is possible for all these conditions to exist and that without inflammation. I would therefore urge the propriety of small abstractions of blood as of great utility in assisting us in a correct diagnosis in many of these obscure cases.

Dr. Reid says in his work on nervous diseases, "that less slaughter, I am convinced, has been effected by the sword than by the lancet, that minute instrument of mighty mischief." Such an expression coming from an author, shows him to be a very reckless observer and defective clinician.

Let us look facts square in the face, and what is true of one thing may *per se*, be true of another. To-day the anatomy of the human body is just the same as it was fifty years ago. The physiology of the various functions the same. Morbid anatomy the same, and the entire phenomena of inflammation, from hyperemia to gangrene, the same. In therapeutics, fifty years ago, tartar-emetic was a nauseant and emetic; it is so to-day. Calomel was the specific for syphilis, and has kept its reputation untarnished to this hour. Fifty years ago blood-letting was the great antiphlogistic remedium and combater of many of the neuroses. Practitioners of that day were not engaged in cultivating speculative medicine; they were veritable clinicians, close observers of symptoms and treatment. They did not believe in or draw their conclusions from experiments made upon dumb animals, but obtained their knowledge at the bed side of the sick. The speculative and metaphysical medicine of the Germans had not made its appearance; the expectant practice of Todd and Bennett was not born. It is true, that like every other valuable remedy, blood-letting in some hands became a hobby and to a large extent fell into the rut of routine and empiricism, which generated some injudicious use of the remedy. In the hands of such men, any remedy however valuable is liable to abuse and in danger of being carried to extremes. Extremes in medicine, especially in the practical relation to society, are dangerous, while conservatism is usually safe. I am convinced that the great neglect of blood-letting in modern practice is about as pernicious, if not more so, than the lamentable abuse of it in the hands of its friends. Hear what Dr. Tilt, of London, says: "Practitioners of the present day are so hoodwinked by the bug-bear debility, that they fear to ruin a patient's constitution by taking away ten ounces of blood from a patient of average strength at the outset of acute inflammation."

I hold, any average doctor can cure a slight ailment, nature will do the work

if let alone exclusively on the expectant plan, but the highest test of skill is requisite when he comes to confront and grapple with a grave form of disease; those grave forms of *sthenic* inflammation and the profound neuroses that are overwhelming the great nervous centers. No expectant line of treatment is safe here; the edifice is tottering and reeling, and is shaken from center to circumference, and a *shilly-shally*, milk and lemonade practice savoring of homœopathy, will fail in this fearful turmoil. As a clinician you look upon the scene and ask yourself what is to be done. Science answers, subdue the quickened and laborious action of the heart—this excessive vascular or arterial tonus and capillary stasis, and derangement of innervation and nerve centers—down it with the club of Hercules, the lancet. I believe I can say without any bias or prejudice that I have given all the so-called vaso-motor and cardiac depresents in all forms of *sthenic* inflammation, and what I may have accomplished with them I am confident could have been accomplished by blood-letting and with a more speedy return to convalescence.

The modus-operandi of blood-letting is that it procures an effect upon the blood directly and immediately, and upon the system circulating the blood. The obvious effects upon the blood are first, a diminution of the actual quantity circulating in the system. But it don't diminish it in the same proportion in every organ; for the brain is a notable exception. Now the effect this diminution is very transient, the normal quantity is soon restored. But the more important change the pathologist wants is in the quality of the blood, for immediately after venesection the vessels take up watery fluid from all parts of the system (hence valuable in some *sthenic* cases of anasarca) and thus the proportion of water in the blood is increased, and the blood is less stimulating to the heart and arteries. Now in all the process, the quantity of albumin and fibrin is scarcely affected, while on the other hand the corpuscles are diminished in a very notable degree.

The second effect of blood-letting is to diminish the activity of the circulation. Under blood-letting the heart contracts with less power upon its contents, and propels a less quantity of blood into the arteries and capillary system. Here is the important difference between the *modus-operandi* of so-called motor depressents and venesection. Tartar-emetic for instance, slows the action of the heart, by first acting upon its inhibitory nerve, the pneumogastric, whereas, blood-letting slows the heart by first lowering vascular tonus, and acting upon the blood conjointly in relation to its quantity and quality. This gives it the preference over tartar-emetic or any other cardiac depressent.

Summed up, blood-letting physiologically slows the heart, decreases the momentum of blood in the vessels, removes capillary stasis and alters in some respects the constituents of the blood. I know it is claimed by those opposed to blood-letting that all the above can be accomplished by the motor-depressents and cardiac sedatives. Now, if all this can be accomplished by these agents, we must admit that a prolonged circulation and chemical change must take place before these effects are manifested, either for general purposes in the system or for local selection. The so-called anti-phlogistic remedies are slow in their action, and frequently behave unseemly, and at the most are uncertain, whereas blood-letting is prompt and certain in its effects and results.

An indiscriminate use of blood-letting is not contended for. Blood-letting to be efficient requires great discrimination in regard to the type of the disease, time, age, idiosyncrasy, sex, quantity and repetition. Ordinarily it is never done too early, but more frequently too late, and this very fact often brings it into ill repute. Our fathers gave us, as they supposed, very important rules for our guidance in the premises; among the more important was that relating to the pulse.

After I had been in practice about fifteen years, acting upon the suggestion of Lænniae, I discarded the pulse as a guide for venesection, and took the fountain head of the circulation for my guide. I am satisfied from long and careful observation that the heart is the best and safe guide for our conduct and for repetition of the measure. As an example, in abdominal inflammation, either traumatic or paturient, if we rely exclusively on the pulse, we should be very liable to withhold

venesection. This deceptive pulse is one of the most difficult to discriminate and point out the course to pursue. An error here may be fatal to our patient. So I reject the pulse in forming my opinion upon the propriety of blood-letting from its unreliable indications. The stethescope offers a much more reliable and safer indication than the pulse or pain. When the contractions of the ventricles are energetic we may bleed without doubt or fear, if the pulse is low and weak they will rise; but if the contractions of the heart are feeble, although the pulse still retains a certain degree of strength, we must be cautious in its employment. When conjointly, the pulse is very strong and bounding and the contractions of the heart moderately strong, we may bleed with advantage as long as there is not a marked diminution in the noise and impulse of the heart's action. But on the other hand, whenever conjointly the pulse and heart are feeble, we must not open a vein, whatever be the name or seat of the disease. I therefore look upon the stethescope as the best indicator, especially if those difficult cases in the domain of practical medicine, where so much is to be gained by a judicious discrimination, as in the thoracic, abdominal and intracranial inflammations. It may be surprising that the practice of feeling and relying upon the pulse has been so generally followed in all ages. The reasons of the practice are, however, sufficiently obvious. It is very easy of performance, and gives little inconvenience either to the patient or physician. The most scientific can derive from it but few indications and conjectures for blood-letting, but the most ignorant charlatan can without exposing himself deduce from it all sorts of indications.

We have no use for the pulse ordinarily now to determine the normal temperature of the body, nor do we hear any more the old term *choler-mordex*. The pulse I opine is of more value in prognosis than it is in diagnosis or in therapeutics. I have thought that the uncertainty of the pulse gives it a preference with persons of inferior qualifications, over means quite certain in their nature, and which enable the non-professional observer to judge of the skill of the physician by the correctness of his diagnosis and prognosis. Then the mere state of the pulse is not the criterion for indicating the precise state of the circulation in general; it does not certainly indicate its condition in the entire heart, as it only corresponds with the contraction of the left ventricle, which may be regular at the time of taking the pulse, when that of the auricles and right ventricle is irregular; then in like manner the pulse fails as a good guide as to the expediency of venesection. The certainty and facility with which the stethescope indicates the propriety of blood-letting appears to me to be one of the great advantages to be derived from the instrument, and if the points set forth are carefully studied and adhered to, the physician will not be very liable to be mislead in the use of the lancet, but will have a correct basis for his opinions and practice.

I have always acted, in treating human maladies, on the principle that it is best to generalize disease, and to individualize the patient, as every one has a constitution of his own. It has been said with much truth that every man has his own urethra and every woman her own uterus.

I wish to quote a late writer on the subject of blood-letting. "Essentials of Medicine," by Professor Hartshorn, he says: "It must be admitted that blood-letting has more opponents and fewer defenders than at any previous period in medical history. Why is this? By reason of 1, Reaction from previously existing abuse of the remedy, but the abuse of a remedy don't destroy its value. 2, A change in average human constitution as contended for by some, occurring under the artificial habits of civilized life. [This Flint rejects.] 3, False construction and misapplication of recent science. 4; Leadership and fashion.

The reaction has proceeded too far, going from one extreme to another. We should not throw aside as useless all the experience of our predecessors, as if every new fact was necessarily the heir of some dead old one. I hold that false construction and misapplication of observed facts in physiology and pathology have been operative. In physiology by the denial or depreciation of the *active* part taken by the arteries in the circulation, and in pathology by the veiws of Professor J.H. Bennett in regard to inflammation, that of *exudation* alone. Now, when the *exudation* has occurred, can any but palliative or expectant measures be applied

to the management of its changes. But the active concentric determination of blood—the arterial excitement—cannot *this* be essentially MODIFIED by treatment? Yes. By abstraction of blood, we lessen (for a time at least) 1, The *fullness* of the *vessels*. 2, The number of *red corpuscles*. 3, The force of the *hearts impulse*. 4, The force of the *arterial impulse*. 5, The excitement of the *nerve centers*. By each and all of these influences, we diminish the vascular excitement connected with an inflammation and thus I repeat *lessen the amount* of resultant *exudation*, and render, as Paget remarks, its "biography" more normal, its changes less degenerative and destructive.

It is therefore altogether an erroneous assumption of Professor Bennett, and others, that inflammation is a "self-limited process which cannot be cut short nor interfered with to advantage." If there be anything positive in medical experience, I believe the contrary of this to have been established.

How, then, do we *define*, or *classify* the *remedial* action of blood-letting. It is *balancive*. What do we mean by *reducing* treatment? The answer to this question is important. *I do not know of a single case of any kind of disease, in which the indication or object of medical treatment is to reduce the strength or lower the vital powers of the patient's system.* What we aim to *reduce* is *disproportionate vascular excitement or congestion:* to restore the BALANCE of the circulation. It is mere *imagination* that the abstraction of a small quantity of blood *must always* lower the patient's strength. Under some circumstances it actually increases it.

Taking these propositions as established, we may draw blood for, high *sthenic* inflammation. 2, Active congestion, threatening inflammation or hemorrhage. 3, General plethora. 4, *Sthenic* spasm in certain conditions of pregnancy and convulsions. In all cases the practitioner should for himself be the judge of the *effect* upon the pulse. It is remarkable how small an amount will sometimes do a great deal of good."

I have presented the views of one eminent in the profession as a teacher, clinician and a safe and successful practicioner, one who having no pet theory to advance, looks facts square in the face and who draws his conclusions from sound physiological principles, pathology, and clinical observation and facts. He very justly discards the fanciful theory of Virchow,—that stimulation, *irritation* and inflammation are *essentially* and practically, as well as causative, only degrees of the same vital impression.

Then, taking the heart in preference to the pulse as the proper guide, holding that there is physiologically a distinction in the arterial circulation, to some extent separate and apart from the cardiac movement, by *reflex vaso-motor* inervation, or perhaps due largely to their own inherent contractibility (for without this I deem the cardiac movement insufficient to send the blood to the remote and fine capillary system), with this physiological view as a basis, we are prepared to use venesection scientifically and with the very best results in congestions, acute inflammations, spasmodic affections, various conditions of gestation and parturition, and in some abnormal conditions of the catamenial function.

In conclusion, strictly adhering to the foregoing principles, I am prepared from a clinical standpoint to advocate blood letting in the following pathological conditions coming under special pathology. And first, in those cases justly denoted *sthenic* inflammations occuring in constitutions not debilitated previously by bad habits or other causes—in this category are included pneumonia, pleuritis, bronchitis acutus—and pericardial inflammations; acute phlogosis of the brain or meninges either idiopathic or traumatic; the abdominal inflammations traumatic or otherwise—and more especially that formidable variety following parturition, viz: metro-puerperal-peritonitis. And right here I am regarded with a holy horror by the disciples of Todd and Bennett, and confronted with the exclamation, "*dare you use the lancet* here." Yes I dare and will. I have nothing to do with Todd and Bennett, I am governed by my own judgement and clinical observation. "Well, don't you know," says the bacteriologist that *bacilli* alone are responsible for the disease, and it is a veritable septicemia, and a line of antiseptic treatment is the only safe course. Very well, if bacteria are capable of setting up a grave and tremendous inflammation, it is nothing but inflammation I must first combat, then

when I have subdued this Mr. Antiseptic, you can come in and finish up, and remove the products. The bug-bear debility, and weak and rapid pulse would not deter me from the use of the lancet, for I have always found a decided improvement in all the vital conditions after a free and early blood letting. To be of any value it must be early.

A few remarks in regards to the utility of blood letting in the true neuroses In that terrible affection, angina-pectoris. I have the best of results in immediately relieving the heart pang. I have also relieved the spasm with nitrite of amyl, but no quicker or more effectually than I did with venesection. In fact blood letting in those nervous affections marked with cerebral and muscular lesions, is an invaluable mechanical antispasmodic. In a large number of morbid conditions coming on during pregnancy, the judicious use of the lancet is valuable. Also in those nervous and circulatory disturbances following an acute suppression of the catamenia, characterized by severe cephalagia, fullness of the blood vessels, pelvic pain with *dyskinesia*, blood-letting puts a quietus to the whole chain of morbid phenomena, and thereby restores normal menstruation. I might lengthen the list, but let these suffice. A few years ago I concluded to experiment with Mackintosh's practice of bleeding in the cold stage of intermittent fever, though I do not advocate the practice. I tied up the arm while the man was shaking like Beltshazer, opened a vein and took about 16 ounces of blood. While the blood was flowing the rigor began to diminish, and was entirely gone by the time his arm was tied up, and a few small doses of medicine completed the case. In my long experience with the diseases of the Mississippi valley, I can say that I never have bled a patient and afterward regretted I had done so, but on the contrary I have had to regret frequent failures to do so; perhaps being influenced too much by the prejudice of the times, and unfortunately falling into the rut of fashionable medicine.

We have a class of nervous affections which are unquestionably produced by a toxic element in the blood, the proper emunctories have failed to eliminate it from the blood either from temporary functional derangement, or from organic disease. These toxic elements act with great force and danger on the nervous centers; on the brain in producing profound coma, and upon the medulla spinalis producing reflex motor excitement manifested in clonic convulsions. We have such pathological examples notably in *uremic toxemia*, acute sthenic epilepsy, scarlatina, and rubiolia; and I have witnesssed some acute attacks of hysteria following uterine disturbance from sudden suppression of the catemenia. I am convinced that in menstruation there is a toxic element that should pass away with the flow, for I believe, like the kidneys, liver, intestinal canal and skin the menstrual molimen is also an emunctory for the time being, and is of great value in the female economy in this particular.

Now, in all cases of the above type, I know that phlebotomy is a remedy of great value and depuriates the blood, thereby relieving the nervous centers, and the entire nervous system of its hypermorbid excitement by directly draining away the *materies morbi*. By also increasing for a time the amount of serum in the blood, the proper channels are aroused to increased secretion and soon rids the blood of the virulent enemy of the nervous system.

A few cases in illustration (of typical cases) will complete this paper and establish beyond question the propriety of blood-letting in this class.

A. P., aged 46, had served in the army three years, had no sickness while in the service. Weight about 150 lbs; nervo-bilious temperament. All the history I could get of his case was that for about five days before the attack he complained of constant pain in lumbar region, but continued to work on the farm. October 16, 1866, I was sent for to see him; arrived at his residence at 11 P.M. I found him in a state of profound coma with terrible convulsions; his skin had a urinous smell. I diagnosed the case acute *sthenic uremic toxemia*. I secured the services of two stout men to hold him while I tied his arm, and by the light of a lamp I opened the median basilic vein and drew away about 18 ounces of blood. As soon as the blood began to flow the convulsive movements began to subside. After his arm was tied up, they entirely ceased. Consciousness returned; he took a purgative and diuretics and had a speedy

recovery. What would an hypodermic injection have done for this case?

Mr. E. E., moderate drinker; been anasarcous for about one month; called in consultation with Dr. McMillen, of Washington; patient had convulsions; in a semi-comotose condition; urinous odor from his body; has passed no urine for forty-eight hours, none in the bladder. Purgatives and diuretics have been used with sinapisms to lumbar region. I recommended venesection. Concurred in; drew away about fifteen ounces of blood. Convulsive movements immediately subsided with the comotose condition, and in five hours after bleeding he had a copious discharge of urine and made a good recovery. The above were typical cases of uremic intoxication, and unquestionably were restored by blood-letting. One more case and I am done. Miss Ellen L., aged 18; of fine physique; rather inclined to an irritable temper; mensturation normal. Washed off the porch in cold weather at six P. M. in her naked feet and while mensturating. Complete suppression of the flow; spent a restless night. In the morning I was sent for. Found my patient complaining with a severe headache, the pain confined along the sagittal suture, a veritable *clavis-hystericus*. Severe pelvic pains; eyes unsteady, rolling rapidly in their orbits; quivering of the lips, and twitching of the facial muscles ; well marked globus-hystericus, hyperasthesia of the skin described as a pricking sensation. In fact my patient was on the very edge of hysterical convulsions ; acute *sthenic hysteria*. I called for a bandage and began to bleed her. I shall never forget the horror-stricken features of her mother when she discovered my purpose as she remarked "You ain't agoing to bleed her are you? doctors have quit bleeding." I replied, Yes madam,I am; you see I am one that bleeds when I think there is a necessity for it, and there are a few more left of the same sort. Now look and see how soon I will quiet down all this disturbance by taking away a few ounces of blood. I bled her to the amount of 12 ounces. She immediately became calm; headache and pelvic pains disappeared and she went off into a quiet refreshing sleep. In the afternoon ordered sedleitz powder, and a hot foot bath at night. Next morning on visiting her, found she had rested well; purgative had operated, and she was having a fine flow of the menses. Dismissed.

Her mother had a pleasant, serene smile as she remarked: Well Doctor I now believe if the doctors would bleed more they would not lose so many patients. To which I acquiesed.

Let me have your indulgence while I quote a case from Dr. Fordyce Barker, in his admirable work, *Blood-letting in Obstetric Medicine*, 1871; treating of certain exceptional cases of puerperal mania, he says: In February, 1868, I was sent for to visit a young lady the thirteenth day after her confinement. Her puerperal convalescence had been so free from all unpleasant symptoms that I had ceased to visit her. I found her gloomy and taciturn—a very marked change from her usual temperament—complaining of nothing, and refusing to answer any questions. The nurse informed me that the first symptom, which had occurred a few hours before, was a complaint of pain in one of her breasts, and a refusal to nurse her child, which she had been very fond of doing; one breast was somewhat tumefied and evidently painful; her pulse was somewhat tense and quickened. The axillary temperature was 103°. There had been no chill; on visiting her the next morning I found that she had not slept a moment; that she had not nursed her child; or permitted anything to be done to her breasts; or taken one drop of drink, one mouthful of food or a particle of medicine. She was now beginning to talk wildly and rapidly without noticing any remark that was made to her. During the day I visited her very frequently, and at each visit I found her condition becoming worse. In the night following I found her face highly flushed, her eyes red, and she had become very violent, with an astonishing display of muscular power. She would tear off her clothes, and scream incessantly, with a constant repetition of certain phrases, in such tones, and with a 'damnable iteration' as almost to drive every one crazy who heard her. With great difficulty her husband, her brother, and the nurse held her while I opened a vein in her arm. As the blood flowed at first it scattered generally around the room and on the persons of those of us about her. She gradually became more quiet, and sank

down on the bed, and fell into a sound sleep while I was bandaging the arm. Nearly five hours after she awoke, asked for her baby to put to the breast, and she was perfectly cured. After this she did not have a single symptom of disease, and her convalescence was rapid. We estimated the quantity of blood taken at about fifty ounces, although so much was lost at first that we could not judge very accurately. In no case have I ever seen the effects of medical treatment so promptly and so happily curative."

My experience with parturient mania has been limited, having only encountered three cases in my whole obstetrical experience Two were in multiparæ, and one in a primipara. One multipara was almost sanguine from excessive post-partum hemorrhage. Calmatives, with perfect seclusion restored her to health. The other two were well marked cases of a sthenic type In these I early resorted to phlebotomy with the best of results, making the treatment following, consist principally of a combination of hydrate of chloral and bro-potassium with strict avoidence of all mental excitement and with good nutriment.

---

## THE LIMITATIONS OF THERAPEUTICS IN THE CONTROL OF DISEASE.*

HENRY M. LYMAN, M. D.,† Chicago.

It is not a great while since I had occasion to prepare and deliver an address, in which I had the pleasure of calling attention to some of the great and valuable advances that have been made in therpeutics as applied to the treatment of medical cases during the past few years. And under the influence of those brilliant discoveries, I found myself indulging in many optimistic anticipations, which, perhaps, were then too sanguinely expressed.

Subsequent reading and research have led me to feel that while there is much for which we can be grateful, and with which we cannot but be delighted, there is still another side of the picture, to which it is not usual to make reference. It is much more popular and agreeable on occasions like this to come before an audience of brother physicians with some new discovery that shall hold out great anticipations of substantial progress in the therapeutical art, by which we may be able to relieve humanity of diseases and of suffering that previously were beyond the reach of medicine. That is what we delight to do, and what is a pleasure to do, and what we all seek to do on occasions like this, and therefore, the other side of the picture is apt to be neglected, but I hold the other side of the picture is as important for the practical physician for practical therapeutics, as is that which presents the more brilliant prospect.

I have chosen for my subject to-day some of those limitations with which so many of us are familiar, and which we must all encounter in our endeavors to deal therapeutically with diseases. I will begin by retracing some of those familiar difficulties with which all practitioners soon become too well acquainted, and will then advance some of the wider applications of my theme. Let us remember, in the first place, what our experience has been, both personally and collectively, with such a familiar drug as mercury, and its preparations and its compounds. You know how invaluable are these compounds. They are indispensable to the practical physician; it is impossible to get along without them. Yet remember what sometimes happens, unfortunate cases of salivation, destruction of the red blood corpuscles, great debility consequent upon the use of the article, the patient sometimes landing in a condition of great misery and suffering in consequence of the use of this most valuable drug. Let us think of that for a moment. It is important for us while we study the useful properties of a drug, to also accurately acquaint ourselves with its deleterious properties, that we may guard against those injurious results that follow the use of such drugs. Again, take arsenic, an old remedy which we have used time and time again, and we cannot dispense with it. It is

---

* An Address delivered before the Michigan State Medical Society, 1893.

†Professor of the Principles and Practice of Medicine, Rush Medical College.

absolutely indispensable in the armory of the physician, yet remember what effect sometimes follows the use of that remedy. And how a patient who takes iodide of potassium may suffer with coryza, excruciating pains of a neuralgic character involving the territory of the fifth pair of nerves; disordered digestion; impoverishment of the blood; and we could go on with a long train of the ill consequences that follow the use of this most valuable drug. The lesson I would draw from these facts is the importance of becoming acquainted with the deleterious as well as the beneficial effects of an article, so that we may guard ourselves against those accidents that will follow the incautious or untrammeled use of remedies; for if we but acquaint ourselves with both sides of the picture, and know what harm can be effected, as well as what good will be accomplished by the administration of such a drug, we shall not be likely to have an experience of those unfortunate results of the use of the article.

Then, again, take another and familiar remedy with which you are acquainted—salicylic acid and its compounds. Those of you, who have practiced medicine for half a century or more, are familiar with the straits in which the physician was placed when brought in contact with a case of acute rheumatism, every joint, perhaps, in a state of inflammation, pain, swelling, everything that is characteristic of acute inflammation; the patient not capable of being moved, absolutely paralyzed, the approach of his physician or attendant giving rise to paroxysms of agony. You know that was a familiar scene in former times before the introduction of salicylic acid, and what a transformation was wrought in the therapeutics of rheumatism when the effects of those drugs were recognized and made known. And you all remember how, as time went on, we again find out that those drugs, so useful to arrest pain and cause a cessation of inflammatory symptoms, so potent to restore the patient to a condition in which he could use his locomotor apparatus and sleep without resorting to opiates in large doses, you will remember that those also began to manifest in your experience various symptoms, not only gastric irritation, loss of appetite, indigestion and all such consequences of the administration of the drug, but also, alarming symptoms of heart failure, as a consequence of the incautious administration of those potent remedies, rendering it necessary, you see, to study most carefully, the evil that might flow from an incautious or excessive administration of those most valuable remedies.

Another invaluable class of remedies—the bromides. You are familiar with their use in every day practice; how indispensable they have become to the practical physician who deals with nervous disorders, notably with epilepsy; how under the influence of the bromides it is possible to arrest sudden cases of epileptic paroxysms, to postpone the attacks, and to render them less frequent, less formidable, sometimes to effect absolute cure. And yet, remember how with all of us, in our earlier experience, perhaps, more than in our later experience, it was not a common thing to witness a temporary degradation of the intellectual faculties, under their influence. All of which shows how important it is to have fully before the mind, continually and always, the possibilities of evil that may flow from the incautious or excessive use of the most powerful, and consequently the most useful drugs that are known. The same thing may be said also of some of the other therapeutical measures to which we have recourse in the treatment of disease. You know that it is not an uncommon thing to call in the aid of a surgeon for the treatment of certain maladies, notably of epilepsy, and how surgical measures have been employed, and how, in spite of all these methods you have seen relapses occurring. In certain cases of epilepsy treated with drugs, though the paroxysms of the disease may have been suppressed, and the patient apparently cured, or if not absolutely cured, greatly relieved for a long period of time, the patient will sometimes tell you that after all he would prefer not to continue treatment any longer. Not because dissatisfied with your methods of measures, but because he feels so much better when the disease was allowed to run its natural course, and because an explosion or convulsion at certain stated intervals, seems to give absolute relief, showing that the wisest and best therapeutical methods may nevertheless absolutely fail in giving to the patient that degree of comfort and satisfaction which we desire, and which we consider

the mark of successful treatment.

Going a little further, and considering not merely the use of individual drugs, let us consider somewhat the result of what may be called therapeutics on a large scale as applied to communities, and there we shall be struck very forcibly with the evidences of the importance of having reference to the shady side of our methods as well as to the bright and promising features of the measures that we recommended and employ. Take, for example, such a disease as tuberculosis. Now, tuberculosis is recognized as an infectious disease. We know the cause of it, and we know that that cause is an exotic parasite that becomes lodged in the body of the patient, and that the manifestations of the disease are the consequences of the growth and multiplication of that parasite in the body. And we know that this parasite may find its way from the body of one individual to that of another who is healthy, and who may thus be transformed into a diseased patient. Suppositions of this kind have been prevalent for ages in the history of the world. We have, in our own way simply demonstrated what was formerly a suspicion, and what was in the minds of many more than a suspicion.

It is in the treatment of such diseases as this that we may learn something with regard to the importance of having reference to the possibility of doing harm as well as good by the methods that we emyloy. Take, for axample, the experience of the Italians during the last century. One hundred years or more ago, tubercular consumption was regarded as a communicable disease. It was dreaded almost like the plague, like leprosy and small-pox, and when a person was infected with tuberculosis, he was driven from society, became an outcast. In the city of Naples, the most stringent laws were enacted for the preservation of the community from the ravages of tuberculosis. If a physician detected a case of pulmonary tuberculosis among his clients, he was obliged at once to communicate the fact to the sanitary officials of the city under pain of banishment from the city for ten years. The unfortunate patient was made an outcast. He was excluded from all possibility of association with his fellowmen. His family consequently were driven out from the society of their fellows and were reduced to destitution and misery. Employment became impossible for such a patient, and when the poor fellow died, the house in which he had deceased was literally eviscerated; the plastering was removed from the walls, the wood-work torn out, and everything built over. And yet what was the result? Tubercular consumption in that city was a more fatal disease than it was elsewhere, and you can see, after a little reflection, why that should have been the case. For when an unfortunate was thus treated and thus deprived of employment, the horrors of starvation overcoming him and his family in addition to the ravages of the disease, a fatal consequence would be much more inevitable than under other circumstances. So that certainly we have, in our public dealings with disease, to consider the possibilities of harm as well as of prospective good in the methods we employ.

In the same way we must keep in mind also the possibilities of harm from the measures we employ on a large scale against infective diseases that are foreign to the country. We have before us the possibility at this moment, of being compelled to fight against the introduction of cholera from the old world. On looking over the country, it is the opinion of those conversant with the matter, that it is important to draw a cordon around our borders, and to subject all incomers from without to a most rigid inspection, for the purpose of keeping out the disease. That may be the better way. But you must always also keep in mind the other side of the picture; that just in proportion to the stringency with which we carry out the quarantine method, and just in proportion to our success with which we are able in this way to bar out a disease like this; just in proportion to our success in that direction will become our reliance on that as a method of protecting ourselves against disease; and experience shows that where nations rely upon quarantine as a means of protecting themselves from disease, other methods are neglected, and filth accumulates in the crowded quarters of the country. Sanitary improvements and hygienic arrangements for the promotion of health are neglected, and everthing falls into an unsanitary condition. So that when teaching quarantine measures for the exclusion of epidemics like cholera, we must see to it that we do not fall into a

fool's paradise of false security that will grow up from reliance upon stringent quarantine.

Let us also consider our own domestic arrangements for the promotion of health in the communities where we live, and let us take careful thought as to the measures which we employ, and see whether there may not be a possibility of doing harm as well as good when undertaking to legislate for the health of the community, and endeavoring by official action to improve the health of any given country, or cities and villages. Here the greatest caution is necessary, for the reason that much of our legislation in this direction is based upon the experience of epidemics—experience that has been gathered during epidemics of fever and of cholera, typhus fever and yellow fever, epidemics of brief duration, during which great efforts are put forth for the arrest of the disease. And out of the experience that has been thus gained grows up a certain amount of precautionary legislation for the promotion of public health. Now, experience that is thus gained under the stress of alarming excitement, and especially experience that is derived from brief epidemics in small communities, in rural localities where but a few families are subjected to the disease, is seldom a safeguard for the exigencies of ordinary life. We ought to be cautious lest in the application of such experience we do harm as well as good.

Take, for example, the experience of certain English cities with regard to the notification of disease. You know that England has probably the most perfect sanitary system of any country in the world. The dense population, the great wealth of those communities is such that they have been enabled to carry out on a larger scale and in a more perfect manner than in any other part of the world, what may be called a series of sanitary experiments for the promotion of public health, and it is to their experience that we may look for the most valuable information on many of these points; so, therefore, let us take what that experience shows with regard to the public notification of disease. You know it is considered one of the panaceas for the arrest of epidemic diseases that there be a health official to whom shall be given immediate information of the occurrence of infectious disease anywhere in his jurisdiction, so that he shall at once know of the presence of cholera, typhus, scarlet fever or any other infectious diseases that may be subjected to sanitary supervision. And then you know that in many communities it is customary for the officials to at once take active measures to prevent the spread of those diseases. Now, we must here be on our guard, for it is just here, when we are dealing with what may be called domestic pestilences, that we are liable to fall into error through blind reliance upon experience that has been acquired under extraordinary circumstances during the prevalence of occasional brief epidemics that quickly disappear and are soon forgotten by the community.

In England this method of notification of the presence of disease in the community has been introduced, but not as an universal measure throughout the whole country. This was a very fortunate thing, because it gave an opportunity for the comparison of methods. In those localities where the practice of notification was introduced, every effort was made to secure an efficient execution of the law; and in this way a great amount of valuable information has been secured. In other sanitary districts, notification of disease was not introduced, and the old order continued. An opportunity was thus afforded for the comparison of results between those districts in which notification was enforced and those in which it had not been introduced. Recently a statistical comparison of this sort was made by the statistician of the general council, one of the high officials of the sanitary department of England. A remarkable surprise was afforded by this investigation—one of the numerous surprises that attend our first and imperfectly enlightened experiments in sanitary administration. It was found that, instead of the great advantage to public health that had been anticipated in the districts where notification had prevailed for a number of years, the decline of infectious diseases in those regions was less marked than it was in districts where the old system of non-notification had continued. The result was a surprise to all who were interested in the subject; and yet it illustrates most perfectly the fault which I have been urging upon you, that there is

a shady side to our therapeutical methods, and that we must study carefully that shady side, for if we cannot always effect positive benefits, we at least should endeavor to avoid doing harm.

If you will reflect for a moment, you will discover the cause of the difference in favor of non-notification: As soon as a case of scarlet fever or measles, or any other infectious disease manifests itself in the household of a workman, mechanic, shopkeeper, or person whose daily labor might be interfered with, or whose means of livelihood might be impaired as a consequence of notification of that disease, every inducement exists for the suppression of information. Consequently a system of concealing infectious diseases grows up, as it does in this country; as it does in every large city; for it is not difficult to conceal the presence of common diseases among a crowded city population. Diseases thus concealed are far more likely to spread than if their existence is frankly confessed.

Another very interesting fact is brought out by the study of the statistical returns of England. We are told that in England—as in other countries—there has been, during the past half century, a decline in the prevalence and the mortality of infectious diseases, and we are told that as a consequence of this decline, there is a prolongation of the average duration of human life. The average duration of human life is greater than it was fifty years ago. That seems like a very gratifying result, but when we come to examine the statistics more closely, we find that this statement is delusive; that there is another side which we must take into consideration, viz., that the apparent increase of life is due to the diminution of mortality from infectious disease among young children. Counting the increased number of years lived by these young children, at first sight it appears as if there had actually been a lengthening of human life in England, but side by side with that gratifying statement comes out another fact. While the infectious diseases have diminished in mortality, other diseases not infectious in character have increased in number and in fatality; and worse still, that whereas formerly many persons lived to a great age, the number of those who reach advanced age is less now than formerly in proportion to the population. In other words, more men and women die in middle life than they did formerly. Now that is a most unfortunate result, and it should lead us to hesitate before considering the reduction of infant mortality as an unmixed good. For what does it mean? It means that in middle life, the husband, the father of the family, the one upon whom a large number are dependent, has fewer chances of living and supporting those who are dependent upon him than formerly, before the introduction of all these modern improvements.

This is the shady side of the picture which must not be ignored. Does the recognition of these facts mean, however, that we are to condemn the measures that have brought about such results? No. We need never become pessimists as a consequence of these revelations, but we should endeavor to study more thoroughly the conditions that control life, that we may be enabled to understand more completely and perfectly how to improve the health of the community as a whole, and how to bring out all the forces that operate in behalf of life and health, instead of merely attacking conspicuous but really insignificant evils. We should study more thoroughly, in connection with our therapeutics, the evils that may be done to individuals by particular methods. We need to study more thoroughly the social conditions which are active when we attempt to control and regulate the movements of disease in a community, in order that we may learn how only not to save the lives of children, but how to give increased strength to the father and mother that they may live past the period when their children are depending upon them, that they may live to see the fruits of their labor, and to enjoy in good old age the means of improving the national welfare.

## VOCAL PHYSIOLOGY AND SYSTEMATIC VOICE TRAINING FOR THE PREVENTION OF DISEASES OF THE LARYNX.*

J. WALTER PARK, M. D., HARRISBURG, PA.

The State Medical Society of Pennsylvania in 1883, passed a resolution that there should be annual alternating addresses on the subjects of ophthalmology, otology and laryngology, but for various reasons, laryngology was omitted in 1889, hence the first and last address on this subject was delivered by my esteemed friend, Mr. Charles E. Sajous, of Philadelphia, in this city, seven years ago. In looking over his very able address, I notice he pointed out to you the importance and relationship of laryngology to the general practitioner, as well as some of the advancements in laryngology up to that time. I will endeavor to-day to give you a continuation of the advancements on this subject, but in a somewhat different line of thought, viz: the necessity of systematic physical voice training in our public schools and colleges for the prevention of some of our most prevalent diseases of the larynx. This subject has lately been considerably agitated by some of our most eminent specialists in England, France, Germany, Scotland, Ireland and America, and no doubt will sooner or later result in the systematic teaching of the proper methods of breathing and speaking in our primary schools and the systematic training of the voice in all academies, colleges, and higher institutions of learning. The object of this paper will be at least in a measure attained, if I can arouse sufficient interest in the medical profession in general, that they will give this subject serious consideration, and advocate its principles among parents, and heads of families, who have children attending schools and colleges, for by so doing good results are sure to follow. If the governing and controlling powers of institutions of learning have their attention called to this subject by physicians and scientific men in general, quacks or charlatans can no longer impose upon the credulity of the public by traveling around through the country teaching false methods, etc., when most of them do not even know the first principles of systematic voice training.

Let us take the child in its infancy as an example to begin with; when it first begins to utter audible sounds it trys to imitate its mother, nurse, or teacher, and trys very hard to formulate sounds into intelligible speech. Years are required to teach a child to phonate properly. Parents should, therefore, devote a great deal of their spare time in teaching their children how to formulate sounds into words, and articulate them properly, for by so doing, they assist them in acquiring more easily and quickly that which otherwise they would not acquire except by a great deal of extra hard labor. At the age of four to six years a vast amount of good can be accomplished by the parents previous to sending them to school, in the various breathing exercises and the proper method of pronouncing words, and to correct them for every slang phrase they may utter. When a child is sent to school, it is generally taught the art of writing by the proper coordination of its muscles in using the hand, as well as the proper position of the body while at its studies. If we thus teach them the proper method of using the muscles of the hand and body, why should we not have a teacher of vocal physiology to teach them the proper method of breathing, by chest, nasal and respiratory exercises, opening and closing the mouth, the modulation of the voice, etc., pronouncing words properly while in the act of phonation. This training should begin in the primary schools, and be continued with the proper advancements in the art, as the child advances in its studies, and extended to the time it has completed its collegiate education. There are very few colleges to-day that properly train the vocal powers of their students, and as a result a good orator or elocutionist is seldom found among their graduates; and likewise there are seldom heard on the

*Read before the Pennsylvania State Medical Society, 1893.

pulpit, the platform, the stage, and at the bar, men who as specimens of physical voice training are able to speak for an hour or two and not suffer hoarseness or fatigue of their vocal organs. That is the time they should have full control of the respiratory movements of their lungs, know how to attack words at a proper pitch of the voice, and how to control their vocal cords, etc., without producing fatigue and congestion of the larynx and pharynx, which always follows when not judiciously used. Violently exercising the voice in the wrong register, and in an improper tone of the voice, must eventually produce physical harm or disease to some parts of the larynx.

The physician must first skilfully perform his duty in seeing that the pupil can perform the proper nasal respiratory movements, by examining his nose and naso-pharynx, and removing all adenoid vegetations, and treating any existing hypertrophic rhinitis, or hypertrophy of the tonsils; as well as take notice if there are any existing anatomical malformations which might interfere with the development of proper articulate language. Stammering is most always a result of failure to observe properly, and of improper methods of teaching a child. The naso-pharyngeal diseases just referred to are also occasionally causes. The physician and specialist should first call attention to, and point out all defects in an anatomical physiological and pathological point of view, and if possible correct any existing defects and then place the pupil in the hands of the scientific voice trainer. Pharyngitis is often produced by spasmodic, jerky respiratory movements while in the act of attacking a tone, and by not knowing how to economize the breath that is inhaled, thereby producing false, harsh, and congested tones. Raising the pitch of the voice without raising the voice itself is another frequent cause of congestion of the larynx. The part that should be cultivated is the natural tone of the voice in which a person speaks with the least effort. Lenox Browne says "The lungs are the motors of respiration; the larynx the vibrating organ, and the chest, walls, trachea, pharynx, and naso-pharynx the resonating apparatus." The French actor, Talma, always made a habit of speaking in his ordinary tone of voice behind the scenes to some of his fellow actors previous to appearing on the stage, so that he could maintain the same pitch in his voice. This is an excellent habit for all clergymen and public speakers to form. Pharyngeal and laryngeal diseases would be an exception rather than the rule if this were universally put into practice. Madam Seiler says, "that if the physiology of the voice were better known and acted upon there would be few complaining singers and speakers." There is no doubt that the solid basis of the voice is a systematic and proper method of breathing; establish that first, and then begin the systematic training of articulate speech. Dr. Gordon Holmes describes the benefits of vocal practice as follows: "The general well being of the constitution is promoted by voice practice because the wider chest movements accelerate the circulation of the blood, at the same time that they cause a more ample flow of fresh air in and out of the lungs. The obstacle of expiration offered by the contraction of the glottis during phonation confers a greater penetrating power on the pulmonary air, which perforce permeats the minute bronchi, and distends the air vesicles of the lungs more effectively; thus the blood attains a higher oxygenation and greater purity, by which qualities it gains in power of stimulating the vital activities of the various tissues of the body as it courses through them. Effete matters are freely cast off, and new and wholesome material is assimilated in increased amount. The appetite, so to speak, of the various, corporeal structures become more keen, and they are thus subjected to an exalted nutrition. And, moreover, these effects have a certain permanency on account of the gains to the thoracic capacity, derived from the habitual increase of lung expansion necessitated by constant vocal exercise." Chest and laryngeal exercises in a systematic way accomplish some of the same results that are derived from a visit to the higher altitudes, such as Texas, Mexico, Southern California, Colorado, etc.

The question is frequently asked at what age should a child begin to sing, or have its voice trained. Opinions differ materially on this question. Patti was taught systematically by her half brother, Barilli, and first appeared in concert singing at the age of seven years. She sang in concert with trained singers.

Neilson was sent to Wartel when quite young. Jenny Lind was trained for the stage at nine years of age, and (it is supposed) from forcing her voice, lost it at the age of twelve years, but regained it at the age of sixteen. Others who lost their voices in a similar manner, suffered from a paralysis of the arytenoid muscles of the larynx, or vocal ligaments. Manuel Garcia was her trainer after her recovery and the "Swedish Nightingale" soon became one of the world's most renowned singers. Listen to the child as it trys to sing one of its nursery songs; notice the tone and pitch of its voice, and you will soon be able to judge the voice compass; carefully watch it and see that this compass is not exceeded by willful exertions on the part of the child. If it is, stop it at once; if not, allow it to go on by your assistance as much as possible, always being careful that it wearies not in well doing.

You will notice from these remarks that there is no set time for a child to begin to sing, or have its voice trained. That question should be left for your teacher in vocal physiology, or voice trainer to decide.

Another mooted question is, whether a child should sing in a concert or not. Wartel says "if a child is possessed of a not worth training let it sing in a voice concert." By analyzing carefully the opinions of a great many voice trainers we arrive at this conclusion: If a child has an exceptionally fine voice, which by special training would develop into an artistic one, never let it sing in concert until after it has been systematically trained and well developed in all the registers; it can not well go wrong after that. To preserve the sweet and natural tones of the child, to fit it for the stage, the platform, or the bar, it must be carefully and physically well trained when young, and it will then develop into a sweet toned singer, or an eloquent and brilliant orator, and you will thus save many a child from some pharyngeal or laryngeal disease, which it otherwise might have acquired by first singing in concert, previous to having any physical training. Many "might have been" famous singers are never heard, principally on this account.

If you thus carefully develop the delicate muscles of the larynx under the guidance of a scientific trainer, as the athlete trains the muscles of his body previous to entering the race, you not only assist in developing a nation who talk well and sing sweetly, but you assist in saving thousands of people from a premature grave to which they are otherwise inevitably doomed. Vocal physiology and systematic voice training are just as necessary as physical training is as a part of the athlete's daily work.

I do not pretend to say that all who follow these suggestions will never suffer from a cold, a sore throat, or an acute attack of largyngitis or pharyngitis at some time or another, but the probabilities are that fifty per cent of the people who are obliged to consult the laryngologist now, would not be obliged to do so were these suggestions rigidly enforced and observed. The most frequent and common ailments of the voice user from which one may suffer at some time or another are the following—catching cold, sore throat, or relaxed throat, acute and chronic pharyngitis, chronic granular pharyngitis, elongated or relaxed uvula, tonsilitis, and acute and chronic largyngitis.

Having considered the physical necessity of vocal physiology and voice training, some remarks upon the daily life of the voice user, in order to assist in the prevention of laryngeal diseases, are quite applicable before closing this paper.

Most of our eminent authors say that a man's life is controlled 1st, by residence; 2d, by ablutions; 3d, by clothing; 4th, by diet; 5th, by exercise; 6th, by amusements; and lastly by individual habits.

*First. Residence.* It is very important that a man or woman who wishes to preserve a good voice, should live in well ventilated rooms. They should not sleep in the same rooms they occupy during the day. They should be ventilated by day as well as by night. Drainage should be perfect so as to prevent any exhalations from being inhaled, for their injurious effects are soon noticed upon a sensitive and congested larynx. Your residence should be situated rather high and have a southern exposure if possible. As regards climate, some require a dry and high altitude, while others feel best in a moist climate and low altitude. Some can live in smoky and dusty cities, while others must live elsewhere. This should be

determined by the advice of your family physician and laryngologist.

*Second. Ablutions.* This is a subject much debated upon and yet no strict rules have been laid down. The following are among the best. Daily baths are generally advised. In cold weather take a hot bath, rub the body freely with a flesh brush and plenty of soap (a coal tar preparation is the best for cleansing the pores and promoting action of the skin); then sponge the body or dauche it with cold water while standing in the hot, and dry the major part of the body before taking the feet out of the warm water. If there is any fear of perspiration you should lie between sheets for ten or fifteen minutes before dressing. The Turkish bath to the singer has this advantage; the inspiration of hot dry air which is so advantageous in counteracting the effects of cold, damp climates. It should be taken at least two hours after any meal. Put a wet towel on your head on entering the bath, to prevent heat stroke, palpitation, fainting, etc. Have the body shampooed lightly, and if perspiration is not active drink a glass of water. Wash the head as well as the body. Do not take a cold bath immediately afterward, but douche first with water and have it gradually grow colder. Cool before dressing and keep the body and feet wrapped while cooling. Don't take a Turkish bath oftener than twice a week in winter, and once a week in summer. Cleansing the mouth and teeth with cold water before singing and speaking should be practiced regularly. Bathing the throat and back of the neck with cold water is commendable, as it renders the skin less sensitive to cold draughts of air and prevents one from catching cold easily.

*Third. Clothing.* A great deal might be said upon so very important a subject, but I will merely touch upon some of the most essential points. As it is customary when going out to put on a wrap of some kind, in the same manner when entering a room be careful to remove it. Try to keep the temeprature of your body equalized, no matter where you are or where you go. If upon the stage, and rather lightly dressed, be sure to use your wraps while waiting in the dressing room between the acts.

The majority of singers and speakers should use silk or flannel underwear the the entire year, especially if they are inclined to suffer from rheumatism. Others think that underwear woven in combination suits, extending from the neck, to the wrists and ankles, made of silk, gauze, merino, or lamb's wool is the best hygienic underwear that can be worn. It is especially advisable to protect the organs of secretion where damp and sudden climatic changes predominate. Regarding the covering of the neck, no singer should wear a collar that buttons above the level of the top of the sternum. The high collar of the dude, the high and tight collars frequently worn by ladies, are a great hindrance to singers and public speakers; their tendency is to constrict the throat and prevent free movement of the laryngeal muscles, and produce conjestion of the larynx and vocal cords, tonsilitis, etc., and materially interfere with all the movements of respiration.

*Fourth. Diet.* The two chief varieties of food necessary to maintain life, are the nitrogenous and non-nitrogenous. The former is principally found in the meats, and the latter principally in vegetables, starches, sugars, etc. Many vegetables and fruits contain nitrogen, such as apples, peas, white beans, etc., and for this reason vegetarians say we need eat no meats when all the nitrogen we need can be obtained from vegetables. Singers or speakers who do not take much exercise should eat meat sparingly, so as to prevent obesity. A singer should have an interval of about three to four hours and a speaker two hours between a full meal and the time they wish to sing or speak. Some singers or speakers become quite fatigued and tired out by the time they are half through with their evening's exercises; in such cases some beef tea or meat extracts between acts should be taken if possible; or what is still better, a raw egg seasoned with a few grains of salt and a few drops of vinegar swallowed whole fifteen or twenty minutes before using the voice, is an excellent tonic. This is exceedingly pleasant when the voice becomes dry from nervousness. Stimulants such as champagne, whiskey, brandy and the malt liquors should be used very sparingly, for the reaction that follows their use is generally of such a character as to produce a congestion of the vascular supply of the pharynx, and more harm results from their use than the good that is accom-

plished. "Mariani" wine, made from the cocoa leaf, has many vabuable testimonials from eminent actors and singers, but it also should be used with extreme caution, for we all know its active and exhilarating principle is due to cocaine, and who wants to become its slave. Avoid all foods that favor flatulence and have a tendency to interfere with the respiratory movements. All nuts and condiments, peppers, pickles, curries, etc., which have a tendency to stimulate the vascular supply of the pharynx and larynx. At meals tea, coffee and cocoa, should be drunk according to the taste and digestion of the person using it. As a rule they should be discarded. Numerous carbonated effervescing waters when pure are good. Kumyss is a very refreshing and stimulating drink. The light wines, such as Claret, Burgundy, and light Hungarian wines, after a hard day's work are refreshing and recuperative, but total abstinence from alcoholic stimulants of any kind is the best advice I can give you.

*Fifth. Exercise.* Speakers and singers should not neglect their walk in the open air for an hour or two every day. The exercise is frequently neglected for fear of catching cold, but by observing their manner of dress, exercising moderately, and not violently; is an essential which should never be forgotten. A want of sufficient daily exercise soon tends toward corpulency, and congestion of the various organs of the body is liable to be the result, and interfere materially with the movements of respiration.

*Sixth. Amusements.* Swimming, shooting, skating, lawn tennis, fencing, etc., if practiced with moderation are all advantageous. Limit the extent of all amusements to the moment that fatigue begins; if extended to the stage of exhaustion, evil results often follow.

*Habits.* Cigarette smoking is a pernicious habit, especially to singers and speakers. Tobacco in all its forms should be abstained from, principally on account of the inhalation of its fumes into the lungs, and its deleterious effects upon the heart, respiratory movements, and upon the pharyngeal and laryngeal mucous membrane in general.

Each of the main points of my subject might be dwelt upon far more extensively but having touched upon the more prominent ones, I hope that some lasting and favorable impression has been made upon your minds, and that you all may in some manner do your part toward establishing a department for physical voice culture in our public schools and colleges, and by so doing, save many thousands of human lives from a premature grave, by the prevention of many of our most common laryngeal diseases.

---

## BRIGHT'S DISEASE.*

JOHN M. BATTEN, M. D., Pittsburg.

J. McK., aged 40. A moulder. While putting up an iron fence, November 16, 1885, sat on cold, damp ground, the following evening was taken with chills, fever and backache. In a few days afterward I was called in and found him with general anasarca and urine almost suppressed. Upon examination of the urine I found it highly albuminous and his bowels constipated. I ordered him to take a very hot bath, wet cups to back and compound jalap powder in thirity grain doses three times a day. With this treatment continued to suit the varied conditions of the case, the patient recovered in about two weeks.

F. S,, aged 6 years. A male. In June, 1886, suffered with an intractable albuminuria and hematuria, following a mild attack of scarlet fever, which came near ending my little patient's life. The anasarca had extended all over the body, so that he looked more like an alabaster statue than a human being. This condition had developed notwithstanding I had about exhausted all remedies, internal and external, within my therapeutic knowledge, till I had lost all hope of my little patient's recovery. In this dilemma I put my patient on small doses of muriate of pilocarpine, gr. $\frac{1}{12}$, three times a day, when the anasarca and hematuria soon began rapidly to subside and my little patient recovered.

*Read before Penna. State Medical Society, 1893.

R. S. E. A painter, a male, aged 21. Came into my office, on Sunday, January 10, 1891, complaining of dizziness and imperfection in vision accompanied with great pain in the back, loss of appetite, and bowels constipated. He stated that he had been at an oculist's in the month of May last, and that the oculist had ordered him to wear glasses. On this examination I could not make a satisfactory diagnosis. I ordered him home and to bed and to take a dose of compound jalap powder. On the following day I examined his urine which revealed albumin in it. I prescribed iodide of potash, a number of wet cups to back, and milk diet. On January 19, 1891, the highly albuminous urine became very bloody with great pain in the region of the right kidney, so great was the pain that I suspected a calculus in this kidney—I ordered wet cups applied over loins, and ergot combined with the iodide of potash. On February 7, 1891, the blood and albumin in the urine disappeared, sight became normal and patient recovered.

This patient no doubt had had albuminuria since May, when he was fitted for glasses. He gave no cause other than his business for his sickness.

In albuminuria with anasarca following scarlet fever I have found the following medication successful in many cases.

℞ Submuriat Hydrargri..... gr. iv
Pulv. Jalapæ..... gr. vj
Antimonii et Potassii Tartras..... gr. ¼

M. ft. pulv. in chart. dividenda j. Sig.—To be given to a child five years old. After the bowels have been moved freely put the patient on

℞ Potassii Nitratis..... 3j
Tinct. Digitalis..... f. 3ij
Aquæ..... f. 3vj

M. Sig.—A tablespoonful carefully given every 6 hours The frequency and size of the dose may vary according to age and condition of the patient. A hot bath may be given daily to encourage diaphoresis. The patient should be kept in bed.

M. B. A boy, 5 years old. Anasarca, convulsions and albuminuria following scarlet fever, patient very sick—I followed the above line ofmedication and my patient recovered.

I have found that the tincture of the chloride of iron given in suitable doses together with fresh sweet cider *ad libitum* in the convalescence of scarlet fever to be very useful remedies in preventing albuminuria. Patients should not leave the bed too soon after an attack of scarlet fever.

On Friday, October 24, 1890, R. S., aged 11 years, female, came into my office with the assistance of her mother, after having convalesced from a severe attack of typhoid fever. Her gait was shuffling, with right shoulder depressed, she complained of backache, colicky pains in bowels, loss of appetite, and inability to walk erect. I ordered her home to bed, dry cups to back and hot poultices to bowels. The following day I found albumin in her urine. I ordered her nitro-glycerin internally, milk diet, dry cups repeated to the back and hot poultices continued to the bowels. Under this treatment she did not improve. November 1, 1890, I substituted iodide of potash in five grain doses for the nitro-glycerin and November 21, 1890, the urine became normal, the shoulder resumed its wonted position, the shuffling and uncertain gait disappeared, the appetite improved and patient recovered.

The cause of this girl's sickness was obscure because of the difficulty of determining as to whether the disease of the kidneys might not have been secondary to a disease of the spine which I first suspected. I finally concluded and correctly too, that the drooping right shoulder and shuffling gait were secondary to the disease of the kidneys.

In 1872 I examined and prescribed for a case of chronic albuminuria and anasarca in a man aged 50 years, addicted to alcoholism. I remember that my prognosis at first of the case was not very encouraging, but to my utter surprise and entire satisfaction the patient recovered. My treatment at first was compound jalap powder, in suitable doses two or three times a day, till the anasarca was relieved, when I put him on ten grains of iodide of potash three times a day till he recovered. The rapidity with which he recovered under a specific treatment would point to a syphilitic taint which I have no doubt he had.

On Friday, March 24, 1893, I was called to see P. D., aged 37. A saloon keeper—intemperate—occasionally got intoxicated and would remain so for a week—high liver. When I saw him he had been sick for about a month under the care of a doctor, but continued to get worse till the urine was almost suppressed and highly albuminous—and there were anemia, ascites, general anasarca of the body, constipation, orthopnea great tension of heart's action, and cough. I ordered the patient to take a hot bath, go to bed and

then commence to take thirty grains of compound jalap powder every eight hours. I continued the hot baths once every day and compound jalap powder as directed for about a week till ascites and anasarca disappeared.

Then I put the patient on a tablespoonful of Basham's mixture of iron with five drops of tincture of digitalis every eight hours, one drop of nitro-glycerin in nine drops of absolute rectified spirits of wine every eight hours, alternating with the Basham's mixture, and also dry cups to back three times a week. The bowels to be kept open once or twice a day, with the compound jalap powder, and the patient to be kept on milk diet. The albumin not diminishing in his urine as rapidly as I had hoped it would do, and suspecting my patient might have had syphilis, although he positively denied ever having had that disease, on April 17, in addition to the other treatment I put him on ten grains of iodide of potash every eight hours, which iodinized him. After my patient had suffered with intense headache, swollen face, and eyelids, scanty urine, and hoarseness for three days, and after he had taken a drachm and a half of iodide of potash, I suspended all medication for twenty-four hours and wet cupped my patient over the loins. At the end of this period I resumed the Basham's mixture, tincture of digitalis and nitro-glycerin. The urine commenced to flow and my patient became more comfortable.

Sunday, April 23. The urine for the first time since I saw patient is free of albumin and he passes about three pints of that fluid daily, his appetite is good, tongue clean, and says he feels well. The specific gravity of the urine is 1,000—the bowels move once or twice a day by taking a wine glass full of Vichy water three times a day.

The following day the patient was up and about the room and passed three pints of urine with ten (10) per cent of albumin in it. He continued to be up and about his room and to pass the same amount of urine daily but the albumin in it ranged at different times from ten (10) to twenty (20) per cent. till Friday, May 12, 1893, when the urine became clear, straw colored, and free of albumin. Specific gravity 1,010. The same treatment has been continued. I think now my patient has fully recovered and he will be allowed to go out during favorable weather. The same diet will be continued for some time.

I wish to emphasize what appears to me to be a fact, that is that there are certain pathological conditions or structural changes in chronic albuminuria which should not be overlooked in making a prognosis of the case. It is a well known fact that a part of one kidney or a part of both kidneys may be diseased, whilst the healthy parts of one or both kidneys may perform the necessary functions of those organs. Again only one kidney may be affected whilst the healthy kidney will perform the functions necessary for both. In the examination of the urine of such cases albumin and casts may be presented and the physician learning these facts by testing the urine will be apt to give an unfavorable prognosis. In the case where only parts of one kidney or part of both kidneys are diseased, the prognosis would be favorable according to the extent of the kidney or kidneys involved.

We should carefully inform ourselves as to what may have been the cause of the kidney disease. Whether acquired or hereditary? If acquired, the causes of the disease should be searched after and if possible eliminated. If sedentary in his habits he should take more exercise. If intemperate in alcoholic beverages he should abstain from drinking them. If he is syphilitic specific treatment should be inaugurated. When the cause is hereditary there are many irregularities in the constitution that are worthy of study and thought, and there are many conditions arising in the course of the disease that may be ameliorated by hygiene, diet, climate and drugs.

Nitrate of amyl and nitro-glycerin relax and dilate the whole arterial and capillary system. Iodide of potash makes the heart's action more regular. Digitalis increases the force of the heart's action, but at the same time contracts the arterioles. Aconite and veratrum viride make the heart's action slower and more feeble. Convallaria makes the heart's action slower and stronger. Hydrate of chloral dilates the arterioles. The volume of blood can be diminished by blood-letting, and by eliminating the plasma of the blood indirectly by sweating, purging and diuresis. Now, no doubt, we can give relief to a patient suffering with Bright's disease by judiciously prescribing the above remedies suitable to the varied

conditions which may arise in the course of the disease.

If upon examination of the urine we find albumin, we may give nitro-glycerin. If there has been a previous history of syphilis, iodide of potash should be prescribed in large doses three times a day well diluted in water, or mercury may be given in small repeated doses, or the iodide of potash and mercury may be conbined. If the bowels are constipated, we may give the compound jalap powder in suitable doses to keep them sufficiently open and soluble to accomplish what may be indicated in the case. If ascites or anasarea has made its appearance accompanied with pain in the back, we should put our patient to bed, apply wet cups to back, order a hot bath to be taken every day by the patient and give nitro-glycerin, iodide of potash or compound jalap powder as may be indicated by the condition of the patient.

If there are indigestion and nausea of the stomach we should direct our remedies to that organ by giving vegetable bitters, diluted muriatic acid, diluted sulphuric acid or alkalies.

If there is irregularity in the heart's action, we should direct our remedies to that organ, if irregular, iodide of potash with small doses of opium. If the heart's action is increased and strong, aconite or veratrum viride may be given. If weak, digitalis. If the volume of the blood is too great, we should give cathartics, diuretics and diaphoretics. In the earlier stages of dyspnea, iodide of potash in five grain doses combined with small doses of opium may effect a relief. In severe attacks of dyspnea dry cups to the chest and the inhalation of oxygen may be beneficial. In the worst cases of dyspnea it may be justifiable to keep the patient under the influence of an anesthetic. If there are convulsions opium may be resorted to; the old doctrine that opium is a very dangerous remedy in Bright's disease of the kidneys is true, yet it is equally true that it is a very useful remedy. If the patient is anemic we should give large doses of tincture of the chloride of iron and oxygen. In certain conditions one of the natural mineral waters such, as Carlsbad water, may be given.

In the later development of the disease we have restlessness, sleeplessness, headache, twitching of the muscles of the face, nausea, vomiting, delirium, convulsions and coma. To relieve these varied conditions we may resort to opium, hydrate of chloral, nitrate of amyl, convallaria, digitalis, caffein, blood-letting, sweating and cathartics.

The diet in the management of a case of Bright's disease of the kidneys is a very important feature. It would seem that nitrogenous ingesta in great part undergo metamorphoses and yielding their nitrogen to be carried off in combination with a portion of other elements under the form of urinary products of a non-nitrogenous diet or one approximating it, in the proper food in this disease notwithstanding Dr. Ephraim Cutter claims that he has seen a full fledged case of Bright's disease of the kidneys restored to health by absolute beef diet in six or more months.

### Rumination in Man and its Relation to the Act of Vomiting.*

Dr. Singer, Vienna, says: The observations upon four ruminants resulted in the following conclusions:

Rumination is the expression of a nervous constitution. The further cause of the act is a relative insufficiency of the cardiac orifice of the stomach, which often opens at a time when a certain amount is contained in the organ. The mechanism of the act consists in aspiration of the contents of the stomach, in the presence of a relaxed cardia and a decrease of air in the thorax, which is produced by the act of inspiration, filling the thorax and at the same time closing the glottis; rumination can be repressed by expiration.

Physiologically and clinically this should be regarded as separate and distinct from the ordinary act of vomiting. The gastric function is inconstant and only of passing importance; the anomalous secretions of the stomach are due to neurotic conditions and require, therapeutically, only symptomatic treatment, while the *cause* of the neurosis is receiving the proper attention.

---

INTERESTING.—Mrs. Peachblow.—"Who is that dreadful man my daughter is talking to?"

Mrs. Seteway (angrily).—"Why, that is my son!"

Mrs. Peachblow (in confusion).—"Oh, I beg a thousand pardons. I thought it was your husband."—*Truth.*

# THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316-18-20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, OCTOBER 14, 1893.

## EDITORIAL.

### THE USE AND ABUSE OF PUBLIC AND PRIVATE CHARITIES.

No one of our great sisterhood of States has a prouder record for its charities, state and private, than has Pennsylvania. Everywhere are those enterprises of private and public benevolence which reflect the broad humanity of her citizenship. Such is the culture, the humane impulses, the local and state pride of her best citizens, that if asked "What constitutes the chief glory of your commonwealth?" they would pass by architectural monuments, the great hives of industry, the institutions that hold the hard earned treasure of struggling busy thousands and would point to the educational and benevolent institutions—those training minds to build the destinies of states, and those relieving suffering, supplying the needy and ministering to the wants of the unfortunate—which proclaim the conscience and heart of her communities and Commonwealth.

In these public and private charities the people have a profound interest and pride. We would neither directly nor by implication charge the management of the affairs of charitable or educational institutions—those enjoying the bounty of the State or the benevolence of private individuals, as tainted with any suspicion of dishonesty. We prefer to discern the good rather than the evil. Fortunately the management of these institutions is, as a rule, put or taken into the hands of men of high character, men whose social standing, public spirit and known integrity are strong guarantees of the faithful and honest discharge of duty.

Yet in connection with this management, economic and other, there are questions deserving of thoughtful consideration. The weaknesses and selfishness of human nature are to be taken into account, for those directing the affairs of these institutions are human—very human. The institutions are for a common benefit—they are of the people, and in them is the people's treasure, given with gladness, but with the desire for its security, its wise and unselfish use. To divert a penny

from its legitimate or intended channel is a moral crime.

Over few of the very many institutions to which the State extends its liberal gifts from the treasure of the people, is there any state censorship. There is no auditing of accounts, no public statement by which the people are informed as to what purpose their money has been applied. The men, usually a small coterie, administering the affairs of these institutions hold a fiduciary relation to the State and community. Yet they are in no manner required to render an account to the State or to any other authority. As these institutions grow in size, needs and demands, the question will grow to be one of some importance, and should now be one of sober consideration as to whether there should not be some supervision over and above the local management; an authority to inquire into the wisdom, economy and methods of administration; an authority through which the people could be informed as to what was done with the money they had generously contributed from their earnings—whether it was all put in "brick and mortar," expended in pensioning a derelict of some old family, or devoted to the specific educational or humane purpose for which it was intended. Only those whose conduct is open to suspicion would object to having their work pass under the severest scrutiny. The authorities and the institutions themselves would gain prestige by presenting to the people of a clean bill of particulars. The life, prosperity and extent of usefulness of all institutions lie in the confidence of the people—it is the basis of their support.

It would be difficult to reason down the suspicion that much of both public and private charity is turned to selfish private advantage. No hard labor, mental or physical, is in greater demand, none is more keenly scrutinized and unsparingly criticised, none deserves higher reward and none receives less renumeration than the labor of the honorable practicing physician. Unfortunately in daily life honor and honesty are terms of relative value, and there is a very strong temptation for a doctor to apply to "professional services" what spare cash a patient may have, and then to lodge and board the patient while under treatment, at some institution sustained by public or private charity. Known instances of such practice have done much to discourage in benevolent work some of the most charitable men of the community. No charity, public or private, can live and meet the ends of its organization when its blood is sucked and its means turned from the appointed use.

In all great cities there are institutions built by generous individual charities. After a generation, sometimes not so long, the inspiration of the founder passes out of the policy of the management and the world is impressed with the idea that the managers are the owners, and that the institution represents their personal benevolence, and too often, there is very hearty feeding upon the treasure by some officials—always, in sooth, charged up to "service rendered," "service as Secretary and Treasurer," "supplies," "repairs," etc. These institutions are the legacies of the public; the people have a title and interest in them, for they are trusts in the use and abuse of which concern the community. It would be wise to keep the public informed of the methods and details in administering these trusts. Whatever inconvenience it might occasion the managers, it would teach the people the difference between genuine and "professional" philanthropy, would show the relations between the giver, the "sieve" and the receiver, and, perhaps, enable the discovery of some "value received" for "services rendered" and charged for.

We have many noble charities under

church management, a management generally broad in its humanities, wise and economical. All the details of such management pass under an examination as scrupulous as that of the affairs of banking institutions. The strong light of honest investigation honors fidelity and intelligence of good management.

Of a truth, "charity suffereth long and is kind."

# TRANSLATIONS.

## CONTRIBUTIONS TO THE STUDY OF EXOPHTHALMIC GOITRE.*

Prof. Müller, Marbourg, the author, gives a description of five cases which he was enabled to study carefully; four of these were acute and one chronic in their course. Of the four acute cases he was enabled to study three post mortem; in two the brain, spinal cord and sympathetic ganglia were carefully examined; the fifth or chronic case, which ended fatally, after a time, was also examined post mortem.

The vagus nerve received careful attention. Three cases studied under the microscope proved the sympathetic intact; the vagus showed in one place a marked degeneration. In all cases changes, such as scattered hemorrhages, were found in the medulla and the rhomboid fossa of the fourth ventricle; these were particularly numerous in the region of the nucleus of the vagus nerve. The author, however, places but little stress upon these changes.

The clinical picture differed but slightly between the acute and chronic cases. The symptoms of this form of disease have been frequently described in various books, which are also given in these cases by the author, to which he adds, however, a number of other symptoms. Abnormal sense of heat, profuse sweats, some slight and passing temperature changes, tremor of the hands, rapid emaciation with great weakness, while there appeared upon the skin abnormal pigmentation, change of voice, vomiting and diarrhœa; the last two, occasional symptoms. The patient suffered from a constant restlessness and excitement

In studying all these symptoms the author concludes that the cause of this disease is not found in one or other portion of the nervous system, but that the brain is undoubtedly also a centre of the affection.

Müller concludes that, without doubt, the etiology of this disease can be sought for as a result of fright or deep distress. In case I. the symptoms followed immediately after a severe fright and ended in the most acute form. In case V. the attack was preceded by deep distress and care, the patient having been made homeless owing to an illegitimate new born infant. One can scarcely understand that the psychical influences should have such a direct action upon the thyroid gland, and the only explanation is that the production of this disease is governed by two factors; first, the anomalous function of the thyroid gland; second, a hereditary neuropathic tendency, or that produced by shock or distress. It is quite probable that neither of these two factors alone would produce the disease,—only when they have combined can this occur. The author is extremely anxious to hear the experiences of others, principally that of surgeons.

### Etiology of Acute Articular Rheumatism.*

Prof. Sahli, Berne, begins this article by stating that acute articular rheumatism is probably an infectious disease, and mentions Huter as the first who called attention to this fact, presenting some points for this statement. He calls attention to the acute rise in temperature. which is usually an attribute

to infectious diseases, and also to the local affection of the joints, in which the resemblance to septic or pyæmic joint affections make the differential diagnosis most difficult. In addition to this he considers the relations between articular rheumatism with endocarditis and the affections of serous membranes, often present, a resemblance to pyæmia. The resemblance becomes still more complete in comparing the case bacteriologically. The granulations on the endocardium, so often present in acute articular rheumatism as well as in pyæmic endocarditis, will show the presence of similar micröorganisms.

In addition to this the author reports a case of typical acute articular rheumatism which was complicated by endo- and pericarditis and pleuritic exudations. The history of the case, fully given, reports the result of a careful pathological examination, which showed the presence of staphylococcus pyogenes citreus in the blood of the left heart, in the swollen bronchial glands and in the various exudations of the pericardial and pleuritic cavities.

The author concludes his remarks by stating that the bacteriological investigation of the reported case, proves that the so-called complications of articular rheumatism (endocarditis, pericarditis and pleuritis) belong etiologically to the disease in question and therefore cannot be regarded as complications but, as localizations; and further states that in a number of other cases of acute articular rheumatism a study of the blood and the secretions of the diseased joints proved the presence of staphylococci.

## *FATTY DEGENERATION OF THE HEART.

The author, Dr. Krehl, Jena, has given much time in studying the various degrees of fatty degeneration of the heart muscle. The only method which gives satisfactory results regarding this question, is the chemical. In order to study this carefully Dr. Krehl took the heart from a corpse 10 to 16 hours after death, cut from it certain portions which were necessary for his study, since the heart contains varying quantities of interstitial fat from 80 to 120 grains in the muscle. This is done by extracting the water from the muscle, then drying and pulverizing the same, and lastly making an extract with ether by which he found that he was able to divide it into lecithin and fat. Previous experiments had satisfied the author that, contrary to former theories, the high temperature necessary for drying did not destroy lecithin in any appreciable quantities.

The percentage of water contained in a healthy heart amounts to about 79.5 per cent. In pathological conditions it is usually increased more or less; the increase is greater in cases of tuberculosis than in phosphorous poisoning or in pernicious anæmia. The quantity decreases in a direct ratio in cases of carcinoma, sarcoma, valvular disease, chronic nephritis and chronic myocarditis.

The substances of the normal heart, soluble in ether vary between 8.3 per cent. to 13.4 per cent., while lecithin fluctuates between 4.2 per cent. to 4.6 per cent. The causes of these variations in the normal heart are unknown. In disease the amount of lecithin varies greatly; the cause of this is also unknown, but the author feels certain that it is not due to the changes in nutrition nor to the presence of fever.

The proportion of fat varies in different diseases; it is increased in poisoning by phosphorus (to double the normal amount), in isolated cases of pernicious anæmia and tuberculosis. No increase is shown in the chronic cases of myo- or endocarditis.

The cause of fatty degeneration is not to be sought in the decrease of oxygen or in the increase of temperature, nor in the presence of local inflammatory heart disease. The author is inclined to accept the hypothesis that the changes in metabolism which lead to fatty degeneration, are due to the circulation of poisonous materials in the blood which are at present not fully understood. The author has studied and illustrated this subject carefully and presents a number of tables to explain his line of thought to the interested student.

# ABSTRACTS.

## THE EARLIEST MEN.

At the recent meeting of the American Association for Advancement of Science, profound interest was awakened by Dr. Daniel G. Brinton's address on "The Earliest Men." How did they come into existence? By special creation. Everything is special. The whole species is made up of special individuals; and their evolution is multiform. Scientific men are agreed that the human race did in some way arise from some inferior animal form—not necessarily monkeys. The transition may not have been gradual, but abrupt—evolution per saltum. We do not find the "missing link;" it is still missing; it may be forever missing. There are different opinions as to how many early men there were. There may have been several distinct centers, but science as well as orthodoxy points toward the conclusion that all men originated from one primal pair living in one definite place. When did these early men appear? A perplexing question. We used to be told that it was 6,000 years ago; but we now know that there were at that time thousands of men living in Europe, Asia, Africa and America. It may be that we have misunderstood tne Biblical record, or that it may have concerned a single branch of the race. It is certain, however, that man appeared late in the geological history of the globe. Human remains have been found in half a dozen places in the world under circumstances that seem to show that man lived in the Tertiary age, but the proof really seems meager. Did man appear during the great Ice Age? The testimony from ancient caverns whose mouths had been sealed by drift, and whose contents lay hidden under stalagmitic floors, as well as that gathered from stratified gravels and other sources, proves that man probably did inhabit the globe during or even before the Ice Age. The date of that age is not exactly fixed, but was probably about 50,000 years ago, although some men of science have assigned a less and others a greater period than this.

Where did the earliest men make their home? Manifestly there were certain conditions requisite. Man requires food and generally some kind of clothing. We many reason by exclusion. The first men did not inhabit an island, for they could never have got off. They did not live where it was very cold, because they would have perished. The greater portion of the northern hemisphere was under water at the time of their advent, hence that is ruled out. They could not have lived in Australia nor in Southern Africa on account of climatic conditions and for other reasons. In short, we find them limited by conditions to the area between the Himalayan Mountains and Spain. Practically the oldest remains yet found have been discovered in the most densely inhabited regions of Europe. The sacred record treats of a particular line of human beings. The fable of the lost Atlantis and the theory of Haeckel as to the submerged Lemurien are not tenable. Eurasia was certainly man's original birthplace.

What did the early men look like? Were they altogether rude? Did they creep on all fours or walk erect? The most expert anatomists have decided, after examining the ancient bones that have been exhumed, that there is no more difference between ourselves and those early men than there is between ourselves now. They were doubtless sturdier. They did not trouble themselves as much about dress as we do. They had reddish hair and probably a ruddy complexion, with blue or gray eyes. Their skulls were about as good as ours, except the famous one of Neanderthal, for which we have less respect than we used to have. In a word, they were men, They knew how to make a fire. Even the very oldest of all men knew that wonderful art. They also knew how to make tools from stone, wood and horn. They were conversant with a variety of instruments and tools. They had weapons with which they killed huge animals. They knew about boats. They had dwellings. They were socially inclined and lived in communities. They were brave and had wars. They endured hardships. They had good hearts

and loved one another. We have positive proof that they took care of the aged and nursed the invalids among them. They had some kind of language and knew something of music. We cannot positively say that the very earliest men worshiped, but if they did so, their worship was spiritual. They had do idols. They had some sense of beauty. They decorated shells. They carved the horns of reindeer and tusks of mammoths. Those first men could travel rapidly. They encountered no very dangerous enemies. We can easily see how there came to be varieties among them, for more changes are now going on than ever before. All shades, from black to blond, are easily explained. We may safely conclude that the early men were essentially human and very much like ourselves, with hearts and brains, hopes and fears, woes and aspirations like our own.—*Scientific American.*

## MEDICAL EDUCATION IN THE UNITED STATES.*

J. COLLINS WARREN, M. D.†

The rising generation of teachers were not content with the antiquated methods of a previous century; they had learned of a new order of things in the centers of medical learning in Europe. As the old generation of teachers went out and a new one came in, the modern ways of teaching grew into a substantial system which had come to stay. Harvard adopted the graded course of three years' study, but she did also far more than that—and in this respect she stands in advance of almost every other school in the country—she lengthened her course to nine months, so that her two terms correspond with those of the other departments of the university and represent a full year's work.

I will not undertake to record the history of the reform in medical education since that time; it is familiar to most of you. The example which has been set to the rest of the country by the University of Pennsylvania and by the College of Physicians and Surgeons of New York is too well known for me to repeat them here.

While criticising, as I have done, the work of a previous generation, I ought to remind you that our forefathers accomplished what they did only by individual efforts. There were no governments, and as a rule no liberal benefactors to back them in their undertakings. Their schools had to be conducted on business principles, with a keen eye to the practical success of their venture. During the past twenty years, it is true, a number of State universities have been established. In the University of Michigan, and possibly in one or two other State universities, the medical professorships like those of other departments, are sustained by the income from the general endowment, independent of fees derived from medical students; but, as a rule, the success of the school has depended upon the patronage which ithasreceived. It may be justly said, therefore, that the whole system of medical education in this country is the spontaneous outgrowth of the work of the medical profession, and that it is due to their public spirit and disinterestedness that so important a department in the educational development of a great nation has been brought to its present state of excllence.

The good work has, however, but just begun. The reform of medical education is still in its infancy. If we are to believe all the glowing announcements which we read in the annual catalogues of the various schools, we might be lulled into a sense of calm security for the future; but, unfortunately, the actual practice of many, I might say a majority, of the schools does not come up to the ideals which are here set forth.

The essential points in the new scheme of education have been well stated by our President, Dr. Pepper.

1. The establishment of a preparatory examination.

2. The lengthening of the period of study to at least three full years.

*An address delivered before the Section on Pedagogy of the Pan-American Medical Congress.

†Professor of Surgery in Harvard University. President of the Section.

3. The careful grading of courses.

4. The introduction of ample clinical and laboratory instruction.

5. The establishment of fixed salaries for the teachers.

In a general way we may obtain some notion of the improvement which has been made by a study of the report of Illinois State Board of Health for 1891. According to this report there are now 148 medical schools of all kinds in the United States and Canada. The number of those requiring certain educational qualifications for matriculation is 129.

The number of schools requiring attendance on three or more courses of lectures was, in 1882, twenty-two. In 1891 the number was eighty-five.

There has been also a gradual increase in the duration of the lecture terms from an average of 23.5 weeks in 1882-83 to 26.3 weeks in 1890-91. In 1882-83 there were eight colleges that had but sixteen weeks; the number of colleges having terms of six months or more is now 111. The number of colleges which have graduated students at the end of the second course of lectures the present year is less than 10 per cent. of the whole number of schools in the country.

There are now in the United States thirty-two examining and licensing bodies that do not give instruction. Although the work of these licensing boards is far from uniform, a great deal has been accomplished by them. There are at the present time fifteen States with Practice acts that require an examination of all persons desiring to practice medicine in the respective commonwealths. These States include nearly 50 per cent. of the entire population. In many States the whole complexion of the medical practice has been changed by the clarifying influences of these bodies. The reports on medical education by the Illinois board, I do not hesitate to say, have exerted a more powerful influence on the movement in education than any other publication which our medical literature has produced.

The effects of these Medical Practice acts which establish a minimum of time spent at medical lectures and provide an examination for those who wish to become practitioners, are shown in the statistics which have just been given. At the present time State examinations are required in Minnesota, North Dakota, Montana, Washington, North Carolina, Alabama, Florida, Virginia, New Jersey, New York, Nebraska, Maryland and Utah.

Millard, who has had experience in framing the act of Minnesota, believes that it would be an improvement upon the Medical Practice acts at present in existence, to separate the two functions of the board, the licensing power and the educational supervision. He thinks that the best interests of the public will be observed by assigning the duties of the State licensing power to the various State Boards of Health. The regulation of all forms of education should, on the other hand, be vested in a central power consisting of a single board, to be known as a State Bureau of Education, with power to regulate all educational institutions granting degrees, together with the power of granting charters and revoking the same; particularly should this apply to all institutions wishing to afford the community any of the various forms of higher or special education.

Having thus sketched the progress of medical education up to the present time, let us now glance at some features of the present system in which it is desirable that further improvement should be made.

The importance of a preliminary training for the study of medicine is a problem which has occupied the attention of our most prominent teachers. That the medical student should have received a fair amount of education goes without saying. The importance of a proper preliminary education, is thus forcibly stated by that most experienced of German teachers, Professor Billroth. He says in reply to the objection to a preliminary study of the natural sciences as a basis of a medical education:

"The educated of all nations should not fail to encourage to their utmost, knowledge and study—in all countries and stations of life they should not fail to maintain the standard which they have set up, both for themselves and others; they should not fail to support the government in all efforts directed toward this end.

"The physician, the lawyer, the school teacher and the clergyman form the nucleus of culture in the community;

they are, especially in the country or small town, the representatives of the educated element of society. The people seek their advice in time of need, and they are their sole source of knowledge in many things.

"To neglect the education of such persons, to lower their mental and scientific standard, to bring them up so that they know no better education than the tradesman, the tailor and the cobbler, would be, in my opinion, the suppression of the educational development of a nation and is a policy both corruptible and immoral in principle, as it would inevitably ruin a nation and bring it prematurely to that point of decadence where it would become the prey of others."

The importance of these views is fully appreciated in Germany, where the professional schools are integral parts of the university, and entrance to the professional schools depends upon the previous completion of the course in philosophy, a course which corresponds to that of our academic degree.

In Dr. Holmes' suggestive article on this subject it is shown that while the increase in the total number of medical students has been very great during the last decade, the increase in the number of "college men" who have entered the profession has been very slight, and in some of the more prominent schools the percentage has even slightly diminished. The author says: "It can not then be doubted that relatively a smaller number of medical students have a bachelor's degree than in 1880, though the education of the average medical student is superior to the average medical student ten years ago." Although the proportion of medical students to students of law and divinity is greater in the United States, the relative proportion has diminished in the last ten years, whereas in Germany in the same period, a period during which medicine has become more of a science and the domain of surgery has increased under antiseptic methods, the proportion of medical students to the students of other professions has greatly increased. The reason for this variation in the proportion of students in the two countries is explained by the imperfection of our system of education. Educators have not had proper control and medicine has not been placed upon that dignified scientific basis which it enjoys in Germany. Dr. Holmes complains that the medical department is neglected by every university in the United States. "It is farmed out or left to shift for itself."

Harvard has recently made an attempt to overcome the difficulty by a modification of the academic course. As Welch points out in an article on this subject. If a young man choose the medical profession he should devote at least four years to medical studies, including the preliminary sciences. If he supplements this with a year in a hospital and a year or two in study abroad, and all this work has been preceded by a college academic course, he would not be able to enter upon the practice of his profession much before the age of thirty.

Dr. H. P. Bowditch, dean of the Medical Faculty of Harvard, has strongly advocated a change which would overcome this difficulty. The average age of students who enter the Harvard academic department, as President Eliot has shown, has been gradually rising during the whole of this century until it has reached nearly nineteen years. The student who enters the medical school therefore finds himself just beginning the preparation of the real work of his life at an age when many of his contemporaries are already engaged in the productive work of their professions. In Germany the best class of students begin their professional studies at a little earlier age than that at which our young men enter Harvard College. As the course of study leading to the degree of doctor of medicine lasts five years, it follows that the German physician is ready to begin practice before he is 23½ years old.

The average age of matriculants at Oxford is 18 years, and it is perfectly possible for an Oxford student desiring to study medicine to begin his purely professional studies before the end of his second year of college life. The dean writes me upon this subject as follows:

"There are many students in our school who have had one or two years of college life either as special or regular students, and these have entered the medical school because they have felt the necessity of getting started in their life work. These men would have been glad to take the A. B. degree if it could have been procured in a shorter time, but

they consider it too dearly purchased when it involves so much delay in beginning their professional life."

It seemed, therefore, reasonable to the medical faculty of Harvard to make the following proposition, namely, that the academic council should consider the expediency of granting the degree of A. B. to all undergraduates who should subsequently take the longest course of study offered at the professional school after three years' attendance in the academic department—the professional degree and that of A.B. to be given simultaneously at the end of the professional course. One of the medical studies at least can be obtained in the usual college curriculum, and general chemistry is frequently "anticipated" by students who enter the medical school. It is hoped, indeed, that this course will soon become one of the "priliminary studies" to medicine. It would be a short step to place one or two more of the scientific medical studies on the list of academic electives, and a whole year could be thus anticipated. The relations of professional schools to the university are not appreciated in the same light that they are in Germany, and the proposition of the medical faculty after much discussion was finally declined. The advantages of a more intimate relation between the medical school and the university are clearly set forth by Welch in the article referred to. The duplication of laboratories is thus avoided, and men of different branches of sciences are brought more intimately together. The important departments of botany, zoölogy, and comparative anotomy cannot fail to have an elevating influence upon the work done in a medical school. How much more rapidly might not original investigation progress when different branches of science work in a common cause. It is here that the great strength of German science and progress takes its origin.

A movement in the same direction is the establishment in our colleges and scientific schools of courses of tuition, intended specially for the benefit of those who intend ultimately to study medicine. Such a course has been planned by Prof. Shaler in the Scientific School of Harvard, and a similar course is offered by the Institute of Technology.

Professor Shaler's course preparatory to medicine consists of two years. In the first year we find physics, zoölogy, botany, general chemistry, rhetoric and elementary French or German, and freehand drawning among the studies required.

In the second year there if botany, zoölogy, comparative anatomy, geology, comparative osteology, physics, qualitative analysis and themes.

It is certainly to be hoped that the medical teachers of the United States will not remain content with the very elementary examinations which are now demanded for those students who have not received a college education.

The advantage of a previous college training is shown in some statistics given by Billings of examinations conducted by the examining boards of the army and navy. Of those candidates who had a college degree 34 per cent. were successful, and of those who had no such degree 28.9 per cent. succeeded. It is interesting in this connection to note that taking the medical schools of Harvard, Yale, the College of Physicians and Bellevue Hospital of New York, the University of Pennsylvania, and the University of Virginia together, 46.1 per cent. succeeded, while for all the rest of the schools in a body 22.3 per cent. succeeded.

Another subject which is receiving more and more attention yearly is that of clinical instruction. The weakness of this feature of medical education was one of the glaring faults of the old system, and arose out of the fact that hospitals were far less numerous than they are at the present time, and that, from the necessities of the situation, the independent origin of the medical school became a custom which has continued almost unimpaired to the present day.

In Boston the medical school flourished for nearly one-third of a century before its teachers realized the importance of this problem. A circular was then issued in 1810, in which the statement was made that "a hospital was an institution absolutely essential to a medical school." Would that all teachers of that time had realized sufficiently that fact and had educated the public to recognize the necessity of such a close relation of the two. Many of the older members of this congress can remember the old-fashioned prejudice which resented the intrusion of students

into the hospital wards. The theory of the trustee of that time was : This money was given for the cure of patients and not for the education of physicians. They could not be persuaded that the two interests were identical.

The change of feeling in more enlightened times was indicated by the benefactor of the great Johns Hopkins hospital. At the opening of that hospital in 1889 Dr. Billings showed the advantage of such a union in the following words:

"It is well known to those familiar with the subject that the sick in a hospital where medical instruction is given receive more constant, careful and thoughtful attention than do those in a hospital where no such instruction is given. The clinical teacher must do his best ; keen eyes will note every error in diagnosis, every failure in results of treatment. Moreover, the very act of teaching clarifies and crystallizes his own knowledge in attempting to explain, the dark places become prominent and demand investigation, and hence it is that those cases which are lectured on receive the best treatment. I need say nothing here on the other side of the question ; the value of properly trained physicians to the community and the necessity for hospital instruction in such training. John Hopkins understood all this, and especially directed that 'in all your arrangements in relation to this hospital you will bear constantly in view that it is my wish and purpose that the institution shall ultimately form a part of the medical school of the University.'"

The reaction in favor of clinical teaching is becoming daily stronger and stronger, and no school can hope to complete with the great schools of the country which does not have control of what is usually called "clinical facilities." This term must unfortunately still be used; for the number of schools which have a hospital of their own is yet exceedingly small. The union between the two is in most of our large cities becoming a more and more intimate one.

Another immense advantage which the possession of a hospital gives to a faculty is the control of appointments. Most schools are now obliged to select their teachers from members of the staffs of hospitals in their city who have services at times of the year which enable them to teach. These individuals are appointed by laymen who have no knowledge of or regard for the necessities of medical education. Faculties thus placed are unable to select teachers of national reputation, as there is no appointing power which enables them to give such a person the material with which to teach. This is a grave defect in our system, and one which the leaders in medical education should not forget to impress upon the profession and the public.

But, while applauding the movement in favor of clinical teaching it is perhaps well at the present time to consider whether systematic or, as it is usually inaccurately called, "didactic" teaching should be abandoned. The discussion as carried on in medical journals, appears to lean in this direction. A course of systematic lectures enables the teacher to cover ground which he would be unable to do, even in a clinic most richly endowed with material. The method of handling the subject differs entirely from that adopted at the bedside, and in a well regulated four years' course I believe the systematic lecture should still retain a prominent place. Clinical instruction should be abundant and of the most varied kind. Instruction of the class in small sections is a most desirable feature of this department. It involves a greater expenditure of time, an increase in the teaching staff and great ability as an organizer in the head of the department. It is the squad drill, however, which brings the student in most intimate contact with disease.

To carry out these ideals necessitates a "plant" far in advance of that which the average school now possesses. No such enterprise can be undertaken without that aid which has hitherto been conspicuous by its absence. I refer to endowments; the valuable paper of Dr. Bayard Holmes already referred to gives some interesting data on this subject. He says:

"The productive funds in the hands of medical schools, both those connected with and those independent of universities in the United States was in 1889, $249,200, while at the same time there was in the hands of schools of theology productive funds to the amount of $11,939,631. The value of buildings and grounds used by medical schools at the same time was $4,047,618, and the theological schools

were accommodated with buildings and grounds valued at $7,762,095. The medical schools had in 1889, 12,238 students who paid tuitions to the amount of $763,761, while at the same time the theological schools enrolled 6,989 students.

I am able to reinforce these figures by an abstract of the statistics for medicine, theology and technology as reported to the Bureau in June, 1892. The medical schools possessed buildings and grounds in 1892 valued at $7,507,937, and productive funds amounting to $611,214. Medical departments of State universities also received State aid in 1892 amounting to $40,500, which, if capitalized at 5 per cent., would be equal to an endowment of $810,000; making a total endowment of $1,421,214. There were 16,731 medical students in attendance.

The theological schools report productive funds amounting to $17,599,979, and stated, at the same time, the value of their buildings and grounds was $10,720,860. They had 7,672 students in attendance.

Technological schools report productive funds amounting to $13,229,940. These institutions received from State appropriations or municipal aid in 1891-92, $747,504, which, if capitalized at 5 per cent., would be equivalennt to an endowment of $14,950,080; making a total endowment for schools of technology of $28,180,020. There were enrolled in the schools of technology 10,921 students, about one-third of whom were in preparatory courses. It will thus be seen that the endowment of theology is increasing at the rate of about two million dollars a year. The technological schools are well provided for, but medicine has scarcely raised its endowment, even at the most liberal estimate, to a million and a half."

Probably the available funds possessed by our medical schools are somewhat larger than these statistics show, but they give the proportions which are needed to impress upon us how little financial encouragement medicine receives. When we realize what a valuable factor the medical man is in the rapidly increasing development of the territory of a vast and prosperous country like ours, it seems as if his claims to receive encouragement should be listined to. He does not build railroads or organize society in new lands but he is in the foremost rank of pioneers, with the complete equipment which our teachers can give to-day, and he becomes a most valuable member of society. He protects the young colony from epidemics; without him State medicine could not exist, and States could not be provided in a bases which could ensure prosperity.

These ideas should be impressed upon our men of wealth and upon the State governments as well. In the meantime it is important that we should adopt as a principle in our new departure in education that the medical faculty should have personal control of hospital wards and management. Let this work begin in a small way at first, but with a view to future development. Such a change can only be brought about by a slow process of evolution. The sooner, therefore, the principle is recognized and adopted, the better. It is difficult for a prosperous school which has abundant opportunities for bed-side teaching to realize this, but it can not develop beyond a certain point until it has established its own independence.

---

### Diarrhœa Caused by Infusoria.*

Of the four cases reported by Dr. Roos, of Kiel, of persistent diarrhœa, the first was due to megastoma entericum and trichomonas intestinalis; the second was caused by balantidium coli; the third by cercomanos homanis; the fourth was produced by a moderately large infusoria which has not yet been described, but could be compared to the oxyuris in form.

The fifth case of intestinal catarrh was complicated with retarded action of the intestines; there were found besides the trichomonas intestinalis and megastoma, those described by R. May. After the continued and regular doses of calomel, the infusoria were killed and the intestinal catarrh cured.

The author does not consider the infusoria as a direct cause of the intestinal catarrh, but feels that they are, in a measure, the cause of the long duration of the diarrhœas.

## THE AMERICAN GYNECOLOGICAL JOURNAL FOR JULY.

Dr. George Erety Shoemaker discusses the

### Non-Operative Treatment of Salpingo-ovaritis; Its Results and Limitations.

The author urges that removal of the appendages should not be performed until other treatment, known to be carefully applied, has failed. He is also guided as to the prognosis without operation by the amount of organized adhesions, and to some extent by the amount of prolapse of ovaries. In deciding whether or not adhesions are insurmountable in any case he advises a patient trial of iodine or ichthyol, boroglyceride tampons, elastic wool packing and careful stretching. Palliative treatment has a field, not only in those cases where the anatomical lesions are not considered great enough to call for operation, but also in a few instances of serious type, where the patient or her family absolutely refuse operation, and where the alternative is preferred of prolonged treatment and the risks of pelvic inflammatory attacks. In regard to the prospects of non-operative treatment in non-purulent salpingo-ovaritis, he says that the idea of a permanent and absolute cure must be dismissed, on account of the likelihood of a relapse. Still, patient and carefully conducted treatment in the intervals between the relapses is capable of very greatly improving all local symptoms, if not of removing them for the time being. In the treatment, every attention must be given to general measures, which will extend all the way from a typical "rest cure" and its attendant round of extra feeding, passive electrical exercise, massage and seclusion, down to the tonic for the factory girl and the advice to go out of doors. Locally, the use of elastic wool tampon, each piece best covered with a thin layer of cotton, to prevent irritation, has a large influence in gradually correcting displacements, and, by supporting the vessels and exerting a mild pressure, in lessening congestion and hyperplasia. While the author has never practiced systematically the massage methods of Thure Brandt, he is confident that, with the milder degrees of adhesion, persistent stretching by the bimanual method, to the limit of safety and of easy toleration, will release many a fundus and many a tube that at first seemed fixed permanently. Where much tenderness is found, a useful addition to the wellknown boro-glyceride tampon is ichthyol, which when made into an ointment with four parts of lanoline, may be put on the tampon against a tender region. This substance seems to have a decided influence over subacute inflammation, and has served to lessen tenderness more rapidly than anything else in his hands. Where endometritis, exists, serious effort must be made to cure it. As far as the author's experience goes, the securing of drainage by moderate dilatation of the cervix and a thorough use of the curette, if done systematically under ether, with a careful preparation of the patient and an aseptic field, is not only not followed by an increase of trouble higher up, but is the most hopeful treatment of endometritis which is not itself dependent on tubal disease. Pessaries are of no use until all adhesions have been released and the organs are first normally replaced; that is therefore late in the treatment. The author lays stress on the point that the so-called conservative treatment of tubo-ovarian disease is a misnomer, and is to be condemned in the more decided cases, especially where pus exists. The treatment outlined above is not applicable to pus cases.

Dr. Marcus Rosenwasser contributes a paper on

### The Indications for Operative Treatment in Extra-uterine Pregnancy.

The author presents the following conclusions:

First.—To prevent free hemorrhage, remove the unruptured sac whenever a presumptive diagnosis is made.

Second.—Operate early in all cases of *free* hemorrhage.

Third.—In cases of *circumscribed* hemorrhage, operate for definite cause: (a) Recurrent hemorrhage; (b) growth of surviving fetus; (c) suppuration of mass; (d) interference of vital functions by pressure.

Fourth.—Early operation is advisable in advanced ectopic pregnancy, but circumstances and individual experience justify deviation from the rule.

Dr. T. J. Crofford reports

### A Fibroid Tumor Complicating Pregnancy.

When the patient was first seen she had been in labor for six days and was too weak, in the opinion of the attendants, for any radical operation. The tumor was so situated that symphysiotomy would not have given relief. It was therefore decided to deliver her by traction, which was finally accomplished after manipulation of the tumor; As the result of manipulation of the tumor, sloughing took place for which the appendages were removed on the seventeenth day after delivery, as, up to this time, the attendant thought the growth to be ovarian. Section revealed its true nature. The patient finally recovered in spite of the fact that the tumor continued to slough and was removed with a portion of the uterus by morcellation.

Dr. Frank W. Talley furnishes a "Report of a Case of Supra-vaginal Hysterectomy by Baer's Method." The patient died of septicæmia from the drainage tube.

The remaining paper is by Dr. J. M. Baldy on "Vaginal Hysterectomy for Prolapse."

## THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

For October. Dr. W. Gilman Thompson contributes a paper on

### A Study of Addison's Disease and of the Adrenals.

As the result of his observations and of experiments on animals, he comes to the following conclusions:

First. That Addison's disease is a condition arising from and dependent upon irritation of the abdominal sympathetic nerves through lesions of themselves, their ganglia, or diseased supra-renal capsules.

Second. In the great majority of instances (fully 80 per cent.) the disease originates as a secondary or primary tuberculosis in the adrenals, and the sympathetic system is either involved by extension of pathological processes, or is functionally disturbed and irritated through the intimate anatomical connection existing between the adrenals and the relatively large number of nerves which they contain.

Third. Actual lesion of the sympathetic system, while far more common than heretofore supposed, is not necessary to produce the varied symptomatic phenomena of the disease. Functional disorder, through irritation conveyed from the adrenals, may sometimes cause all the symptoms—just as in chorea and in many of the conditions of aggravated hysteria, and other functional nervous disorders, we are often unable to find definite lesions.

Fourth. In a certain proportion of cases (not over 20 per cent.) the adrenals are affected by some other lesion than those of tuberculosis, or else they remain normal (in 12 per cent.) and the sympathetic nerves and ganglia are alone diseased.

Dr. Harold C. Ernst contributes a paper on

### The Bacillus Pyocyaneus Pericarditidis.

The author presents the following differences between this organism and those with which it has been possible to compare it:

1. *Macroscopic.* 1. The bluish-green tinge of the gelatin in plate culture, as seen by reflected light, as distinguished from the yellowish-green tinge of the others.

2. The dryness and metallic lustre of fresh colonies and the bluish-green color, by reflected light, of old cultures upon agar agar, as distinguished from the moist elevated fresh colonies, and nut-brown color, by reflected light, of old colonies of the others.

3. The greenish color of the colonies in peptone solutions of varying strength as distinguished from the bluish color of the other bacteria tested with it.

4. The very much greater rapidity and intensity of the reaction of gelatin and bouillon cultures to acids (red color) and alkalies (grass-green).

II. *Microscopic.* The variations in its appearance under the microscope.

1. From gelatin, indistinguishable.

2. From peptone, long, slender rods, as contrasted with short oval ones.

3. On other nutrient media, its general average as a larger rod, which can be made out by comparative examination, but is hardly subject to measurement. It can be seen, however, in preparations from egg-albumin, bouillon, blood-serum, and potato. Only upon gelatin and agar there is no appreciable difference.

It appears, therefore, justifiable to conclude that we are dealing with a distinct variety of the bacillus pyocyaneus, and that Gessard's conclusions that there is but one is unfounded.

The paper is illustrated with a colored print of a cover-glass preparation of pericardial fluid showing the bacillus in comparison with the bacillus of tuberculosis.

Dr. V. P. Gibney discusses the

### Final Results in Tubercular Ostitis of the Knee in Children, Commonly Known as "White Swelling."

The author cautions against the danger of overlooking the disease in its onset and diagnosing the case as one of sprain or rheumatism. The mistake is due in most instances to carelessness in the examination. The joint functions should invariably be tested and compared with those of the other side, both limbs being devoid of clothing. In regard to treatment, he advocates what he terms the protective method, meaning thereby immobilization of the joint until all acute signs have subsided and convalescence can be safely predicted; the use of an apparatus that prevents concussion or jar—in fact trauma of any kind—whether in the shape of a peroneal crutch or axillary crutches. He does not class under protection splints the ordinary extention apparatus, because the adhesive plasters with which traction is secured slip, and the skin and deeper tissues themselves move, so that jar or trauma is not prevented. The apparatus he prefers consists of a posterior splint, with a high shoe on the sound foot.

The paper contains exhaustive statistics as to the results obtained by various methods of treatment.

### Pneumonia of Delayed Resolution and Fibroid Phthisis in Childhood

Is the title of an interesting paper contributed by Dr. George Carpenter of London, Eng. The author states that in his experience, cases of retarded resolution in association with pneumonia have been found, with a solitary exception of basic pneumonia, in those showing an apical, or the upper and part of the lower lobe distribution. In opposition to Wilson Fox, the author insists that bronchial dilatation *per se*, is no more capable of inducing lung fibrosis than inflammatory lung mischief without bronchial attachment is competent to cause dilated tubes. Bronchial dilatation and peri-bronchitis are frequently met with in bronchitis or broncho-pneumonia, but only as part of the disease—of the same morbid inflammatory action.

Cirrhosis of the lungs is not so very uncommon in childhood, and in the diagnosis the position of the heart is of importance. In left-sided lesions the organ may be uncovered, exposing a large portion, or the whole of its surface, with consequent diffusion of the impulse; or contracting adhesions with the lung, the heart may be displaced. The condition has to be separated from chronic

pleurisy with effusion, for, as regards auscultatory signs, there may be but little to choose between them; the position of the cardiac impulse, and the positive or negative results obtained from one or more exploratory punctures, should determine as to its nature. Puncture in cirrhotic cases is not, however, without danger. The disease has also to be separated from an invasion of new growth in the lung. Attention directed to the mediastium, which is almost always attacked, should prevent any difficulty in this direction.

The pneumonia of delayed resolution is, *per se*, not dangerous; it becomes so if resolution does not come to its assistance. In such cases, as far as the experience of the author goes, the rubbing in of some mercurial ointment, such as Scott's ointment, has appeared to him to be of value. In addition the general health must be improved in every way by tonics; iodide of potassium internally, good feeding and change of air. The author does not confine patients to bed under such circumstances. Full expansion of the lungs should be invited by gentle exercise, short of fatigue and of exposure to the east winds and to wet and damp.

With a fibroid lung, all remedies must of necessity be palliative rather than curative. Tonics, suitable clothing, and good food, must be chiefly relied upon. With fair general health there is much less liability to bronchitic attacks. Acute attacks must be dealt with on the usual lines. With bronchorrhœa, inhalations of carbolic acid, creasote, iodine, and turpentine may be used with advantage, and the latter may be administered internally. Excessive coughing must be relieved by opiates and chloral, and indications of cardiac failure combatted by the usual remedies.

A paper on

**The Course and Treatment of Certain Uræmic Symptoms.**

is contributed by Dr. Beverley Robinson. Many attacks of indisposition, due to the excesses of the table, and which are put down in the broad category of bilious attacks, he regards as in reality cases of renal insufficiency. In many instances of obstinate nasal, naso-pharyngeal, laryngeal, and tracheal inflammation, chronic in type, he is firmly convinced that an inactive functional condition of the kidneys is the primary cause of these inflammations. In the evidently gouty cases, and particularly in those where the heart action is good and the tension in the arteries not excessive, colchicine is a more valuable remedy than nitro-glycerine. In instances on the contrary, in which the arterial tension is well marked or excessive and the heart laboring, whilst the quantity of urine is small and low in specific gravity, he believes that it is wise to begin the treatment with nitro-glycerin or the nitrites. In any very alarming expression of this condition, inhalations of nitrite of amyl should first be employed. The author is much opposed to the use of opiates, and especially of morphine hypodermically, in cases of chronic Bright's disease, except in very minute doses. He believes it is capable of doing much harm by locking up the secretions. In those cases however where the heart is the weak organ primarily, and where the kidneys will be greatly helped by cardiac stimulation of an active kind, he is not opposed to the use of morphia in small or moderate doses.

The other papers in this month's issue are: "Further Notes Respecting the Therapeutic Use of the Sheep's Thyroid," by Dr. James J. Putnam; "A case of Panophthalmitis, caused by the Bacillus Coli Communis," by Dr. Robert L. Randolph; and "A case of so-called Pseudomyxoma Peritonei with observations on the Formation of Hyalin," by Dr. Henry W. Bettmann.

# PERISCOPE.

## THERAPEUTICS.

### Local Disinfection.

Chamberland and Tembach (*Am. de l'Inst. Pasteur*, June, 1893) have published the results of an important and extensive research on the above question. Their conclusions are as follows: 1. The Javel water of commerce (a 1 to 10 solution of chloride of lime) and commercial oxygenated water are ten times more active than a 1 to 1,000 solution of sublimate. These disinfectants either do not act, or they act very slowly, on moist microbes at the ordinary temperature, but at temperatures of 50 degrees and over, such microbes are destroyed in a few minutes. It must be borne in mind that whatever be the antiseptic used it is advantageous to allow it to act at the highest temperature possible in order to secure its full activity. 2. Dried microbes are much more resistant. While moist microbes are destroyed in a minute or so, when dried they resist disinfectants for many hours even at high temperatures. Moisture is therefore an important adjunct to disinfection. The authors have found that if dried germs be left in contact with water, and especially tepid water, for an hour, they are destroyed as rapidly as if they had not undergone desiccation. In the disinfection of walls, etc., they therefore advise a preliminary spraying of the objects with water before the use of the disinfectant proper. Another fact brought out by the authors is that a saturated solution of chloride of lime is much less active than one diluted with 10 to 20 times its volume of water. The disinfection experiments were carried out with the spores of anthrax and of aspergillus, with beer yeast and the bacillus typhosus. Other experiments made with

thymol, essence of turpentine, and lysol gave results in no way so satisfactory as those with Javel water or oxygenated water ($H_2O_2$). The former is most satisfactory in that it is cheap, non-poisonous, and obtainable with the greatest ease.

### Injections of Iodoform in Goitre.

Kapper (*Gaz. de Hop.*, September 2nd, 1893) uses a solution containing 1 part of iodoform and 7 parts each of ether and olive oil, which is injected into the goitre after previous disinfection of the skin. The trocar of the syringe is disinfected, and is then plunged to the depth of 2 to 3 centimetres into the tumor, and the patient is told to swallow in order to ascertain whether the cannula takes part in the movements of deglutition, or whether it has not been inserted deeply enough. Immediately the solution is injected the trocar is rapidly withdrawn and the orifice of the puncture closed by means of a piece of diachylon plaster. When the goitre is very large, he injects as much as 6 grammes of the solution at one sitting, in four different parts. The injections were repeated at intervals of four to six days, sometimes on several consecutive days. Local reaction was always feeble. Eight men and six women have undergone the treatment. After ten injections in the course of two months the circumference of the neck was diminished by 6 centimetres at least, and after another interval of two months there was a dimunition of 8 or 10 centimetres. Besides this the discomforts felt by the patients were sensibly attenuated. Six months after cessation of the treatment the improvement was maintained.

## MEDICINE.

### The Pathogenesis of Hepatic Abscess.

Zancarol (*Revue de Chirurgie*, August, 1893) states that he has proved by experiments on animals that dysentery and hepatic abscess are affections of the same nature, and that the pathogenetic factor of this complex organism is a micro-organism. A clinical experience of twenty-five years has convinced this author that the pus of a hepatic abscess is not less deleterious than that of other suppurating organs, and, also, that dysenteric and hepatic abscess are closely associated, so that, though one may not be the cause of the other, both affections are produced by the same toxic agent. In order to establish these conclusions on a scientific basis, Zancarol instituted a series of experiments on cats, the results of which show that both dysentery and abscess of the liver can be transmitted from man to these animals by injections of the pus and intestinal excretions, and that histologically the lesions in the human subject and those artificially produced in the animal are of a like nature. Hepatic abscess, it is asserted, has microscopic origin, the principal factor being the streptococcus. It remains to be settled by future inquiry whether other organisms apart from the streptococcus are capable of producing a similar morbid condition, or whether this organism is the spcial originating agent of the hepatic affection. Dysentery is regarded as an affection of the same nature as hepatic abscess, its pathogenetic agent being the streptococcus. As to the amœbæ which are so often met with in the fæcal discharges even of healthy individuals, these organisms, the author holds, play no part in the causation of dysentery and hepatic abscess. The streptococcus in most instances passes from the intestine to the liver either by the portal vein or the general circulation.—*Br. Med. Jour.*

### * Calomel in Gout.

About fourteen years ago, Dr. F. Grimm (*Deutsche Medicinische Wochenschrift*, Nos. 15, 18, 1893), administered calomel to a patient who was suffering from a protracted attack of gout. The next day he remarked a material improvement and a retrogression of the symptoms. In the meantime he has tried the remedy, in about twenty cases of gout. In some cases the result was astonishing, for it acted like a specific while, in others, the immediate relief was followed by a slower recovery. He ascribes its action to the active peristalsis which results, for, in robust subjects an attack of gout is usually preceeded by sluggishness of the bowels. In such cases is the result the most favorable. The remedy must be so given that active peristalsis will result from the very first dose. One catharsis is generally sufficient to inaugurate the improvement and to continue it. Long treatment is not indicated. After the calomel a carminative may be prescribed. Besides calomel he has also used the yellow iodide of mercury which appears to act more energetically. His observations are confined to acute and subacute, articular gout and its immediate sequellæ. Relapses are not more frequent than after other methods of treatment.

### * Ichthyol in Prostatitis.

Dr. Freudenberg (*Wiener medizinische Presse*, No. 30, 1893) has employed suppositories of ichthyol in the treatment of prostatitis, in 30–40 cases, mostly of the chronic form. In all cases he observed, in a short time, an improvement, and in the majority, a complete cure of the subjective disturbances as pain on defecation, sensation of pressure, on urination, as well as the objective symptoms, swelling or hardness of the gland. At the same time the condition of the patient's mind would improve and his general condition ameliorate. A parallel experience with suppositories of the iodide of potash demonstrated the superiority of the ichthyol. In the cases where necessary local treatment was applied to the urethra, it is of the greatest importance that the ichthyol be properly administered and that it be well distributed throughout the suppository or it

*Translated for The Medical and Surgical Reporter by Frank H. Pritchard, M. D.

will not act well. If used in the prepared hollow suppositories where the requisite quantity is poured into suppository, shortly after introduction, it will melt, the undiluted ichthyol be poured out onto the mucous membrane, and exert an irritant influence on the mucous membrane with pain and stool. He prescribes:

℞ Sulpho-ichthyolate of Ammonium, dgms. 3·6–75. (grs. xlv, ʒjss–ʒi¾).
Cacao Butter, .....gms. 2–2.5 (grs. xxx–xxxvij.)

Mix carefully No hollow ready made suppositories. One may begin with three decigrams, (5 grs.) for a suppository and increase to double that quantity. It is rarely necessary to exceed this dose. Two suppositories, per diem, are to be used, one in the morning, after stool, and the second, in the evening, before going to bed. A third is only to be introduced if a motion occur during the course of the day, otherwise it is not necessary as it was observed that the entire suppository was not absorbed for eleven to twelve hours.

### * Gastric aud other Nervous Symptoms of Neurasthenics.

Drs. Rummo and Braccini (*Semaine Medicale* No. 54, 1893), recommend the following pill, in the gastric and other nervous symptoms of neurasthenics:

℞ Phosphide of Zinc,... ....cgms. 10 (grs. jss).
Bromide of zinc,.....gm. 1. (grs. xv.)
Bromohydrate of Quinine, gms. 1.50 (grs xxijss.)
Extract of Nux Vomica,...gms. 15 c. (grs. ij.)

M. Thirty pills.
Three pills per diem.

### Chloroform as a Tape Worm Remedy.

Dr. Stephen, (*La Semaine Medicale*, No. 54 1893) speaks highly of the value of chloroform in the treatment of tape-worm. With it he has succeeded in expelling worms where the usual tænicides failed him. He used the following, Thompson's formula:

Pure Chloroform, 4 gms..... (ʒj).
Simple Syrup. 30 gms..... (ʒj).

To be taken in four doses, at seven, nine and eleven o'clock, in the morning, and, at one, in the afternoon. At noon the patient is to take an ounce of castor oil. It is well borne even in children.

### * Sulphur in Chlorosis.

Prof. H. Schulz (*Deutsche Medicinische Wochenschrift*, No. 36, 1893) calls attention to the immense importance of sulphur in the human economy and recommends it in the treatment of chlorosis. In cases of pure chlorosis where iron is inactive the general condition is greatly improved by the administration of sulphur, and, after sulphur has been taken for some time, administration of iron could then be commenced. In cases of chlorosis with catarrhal inflammatory states of the digestive tract it is not well tolerated.

* Translated for The Medical and Surgical Reporter by Frank H. Pritchard, M. D.

### * To Prevent the Syncope of Chloroform.

Dr. Casasovici (*La Semaine Medicale*, No. 54, 1893) a Roumanian military surgeon prevents chloroformic syncope by cocainization of the nasal mucous membrane in those about to be chloroformized. This prevents reflex inhibition of the heart and respiration from irritation of the nasal mucous membrane from the vapor of the chloroform. In one patient who presented symptoms of grave collapse during amputation of a foot, after cocainization of the nasal mucous membrane, the other foot was removed, without accident.

### * Iron Subcutaneously in Chlorosis.

Prof. Rummo (*Muenchener Medicinishe Wochenschrift*, No. 36, 1893) has experimented with various preparations of iron, etc., subcutaneously, in chlorosis, and finds the citrate of iron and ammonia to give the best results. The number of blood corpuscles and the amount of hemoglobine rapidly increased. The first symptoms of improvement were noticed after four to five injections, especially were the gastric symptoms and headache the first to disappear. The injections were made under all antiseptic precautions in the interscapular region and never caused either swelling, redness, nor was albuminuria ever observed. The improvement was lasting. In five days the spleen was enlarged.

### * Auscultation in Fractures.

Dr. Vayana (*Medicinishe Neuigkeiten*, No 35, 1893) communicates a new method of recognizing a fracture. In such cases where the usual pathognomic signs of fracture are obscure one may apply a stethoscope to the place of fracture and have the bone at the same time percussed. A rough sound is heard which suddenly becomes weaker the moment that the point of fracture is passed. This simple sign is due to transmission of sound.

### Antiseptic Treatment of Ozena.

The following treatment of ozena is recommended in the *Deutsche medicinische Wochenschrift*, No. 36, 1893): douche the nasal cavity, first, with a solution of carbolic acid. Then insufflate the following powder.

℞ Salol, 10 gms..... (ʒijss).
Boric Acid, 5 gms..... (ʒj¼).
Salicylic Acid, 1 gm ..... (grs. xv).
Powdered Talc. 20 gms..... ʒv).

Or the following powdered:

℞ Muriate of Cocaine, 1 dgm..... (grs, jss).
Menthol, 3 dgms..... (grs.v).
Boric Acid, 2 gms ..... (grs. xxx
Finely powdered Coffee. 1 gm ..... (xv).

A pinch several times a day.

### New Reagent for Albumen in the Urine.

Dr. E. Spiegler has improved his formula for the testing for albumen in the urine. It consists of the following.

℞ Sublimate, 8 gms..... (ʒij).
Tartaric Acid, 4 gms..... (ʒj).
Distilled Water, 200 gms..... (ʒvjss).
Pure Glycerine. 20 gms..... (ʒv).

This preparation keeps easily and will respond to albumen in a solution of 1:350000. A few drops of concentrated acetic acid are added to the urine and the precipitate of mucine filtrated out, if necessary. Pour the reagent into a test-tube and let the urine run down the side of the obliquely held tube. A milk white ring will form at the point of contact. Peptones are not precipitated. If the urine contain iodine it will not respond for a cheesy yellow precipitate of the iodide of mercury is formed which may mask the albumen. It can not be confounded with albumen for it is different in color, and it is soluble in alcohol while albumen is not. As iodine is rapidly excreted it may be easily used by discontinuing the iodine, for a short time, when this very delicate test may be employed.

### *Injections of Glycerine to Induce Premature Labor.

Dr. Edgar (*Wiener Medizinische Presse*, No. 37, 1893) has employed intra-uterine injections of glycerine in two cases to induce premature labor. He injected fifteen grams, ʒiv, between the membranes and the uterine wall. In one case contractions came on after two and a-half hours and in the other in thirty minutes. Of course antisepsis of the vagina is to precede, and it is better to bring the cervix down in order to be certain as to the introduction of the catheter. In the second case a Baine's dilator was placed into the cervix.

### Ergotine and Gallic Acid in Hemopytysis.

Dr. Blaschko (*Deutsche Medicinische Wochenschrift*, No. 37, 1893) in cases of hemopytysis where injections of ergotine were of no service has often succeeded with the internal administration of gallic acid, in stopping the hemorrhage. Therefore, in recent years he has combined it with ergotine in copious pulmonary hemorrhages and with the best of results. He employed the following formula:

℞ Gallic Acid..... 1 gm. (grs. xv).
Ergotine ..... 1 gm. (grs. xv).
Distilled Water
Syrup of Orange Peel..... aa, 25 gms. (ʒvj).
A teaspoonful every two hours.

Where there was a great deal of irritation and inclination to cough he employed the syrup of opium instead of the orange peel syrup and in threatening cases he prescribed a teaspoonful every hour. As this remedy is entirely reliable he was able to dispense with the use of the ice-bag to the chest and injections of ergotine subcutaneously, which latter often lead to suppuration. Small pieces of ice were swallowed and cold milk ordered to be drunk with the greatest possible rest of body and especially of the organs of speech.

*Translated for The Medical and Surgical Reporter by Frank H. Pritchard, M.D.

## SURGERY.

### The Value of the Hands and of the Fingers.

Surgeons have often to estimate the chances of saving injured hands, and the comparative values of hands and fingers. According to a scale of value furnished by the Miners' Unions and Miners' Accident Insurance Companies of Germany, the loss of both hands is valued at 100 per cent., or the whole ability to earn a living. Losing the right hand depreciates the value of an individual as a worker 70 or 80 per cent., while the loss of the left hand represents from 60 to 70 per cent. of the earnings of both hands. The thumb is reckoned to be worth from 20 to 30 per cent. of the earnings. The first finger of the right hand is valued at from 14 to 18 per cent., that of the left hand at from 8 to 13.5 per cent. The middle finger is worth from 10 to 16 per cent. The third finger stands least of all in value; although like other useless members of the community, it is surrounded by riches, its value is only from 7 to 9 per cent. The little finger is worth from 9 to 12 per cent. The difference in the percentages is occasioned by the difference in the trade, the first finger being, for instance, more valuable to a writer than to a digger.—*Med. News.*

### Separation of the Lower Femoral Epiphysis.

Mayo Robson, after referring to the scant attention paid to this subject in the text-books, gives cases to illustrate this condition. Extreme direct violence is usually the cause. The displacement depends on the direction of the violence, but also on the attachment or otherwise of the gastrocnemius tendon to the lower end of the upper fragment. The shortening, the projection of the lower end of the diaphysis in the popliteal space, the displacement of the epiphysis on the front of the femur, and the interference with the circulation, together with the cause of the injury and the age of the patient, form a group of symptoms pathognomonic of this fracture. Robson advises first reduction under an anæsthetic, which might be facilitated by division of the tendo Achillis: after reduction either the long splint with weight and pully or the double inclined plain might be employed. Should reduction be impossible, then excision might be practiced; but if the large vessels be ruptured or gangrene occur, amputation is the only resource.—*An. Surg.*

## OBSTETRICS.

### Intraperitoneal Ectopic Gestation.

Houzel (*Progres Medical*) relates a case where the pregnancy was, in his opinion, clearly peritoneal. For the last three months of its life the fœtus lived free amongst the intestines, without any investing capsule, anatomical or adventitious. It could even kick the liver, and caused great distress to the mother by disturbing the intestines. The pressure of the fœtal head set

up severe pain in the left iliac fossa. The child passed meconium over the intestines. The placenta was firmly grafted on to the bowel. Nevertheless, in spite of the free fœtus and adherent placenta, the peritoneum was not inflamed. The child died at the end of the ninth month. The placental vessels were extremely large and continuous with others belonging to the intestine over the area where the placenta adhered. Houzel could not remove it, as immediate hemorrhage would have been unavoidable, and intestine does not contract like the uterus. As there was no sac, plugging was not attempted. He also feared to close the abdominal wound entirely, lest the peritoneum might prove less tolerant than before the operation. He preferred to leave the lower end of the wound open, to drain and to detach the placenta when it became evident that there was no fear of hemorrhage. The mother recoved.

## GYNECOLOGY.

### Testes in a Subject otherwise Female.

Kochenburger (*Keitschr. f. Geburtsh. u. Gynak.*, vol. xxvi, part 1, 1893, p. 73) publishes a case not absolutely unique out of high interest. The patient was 23 and had never menstruated. When 25 she observed slight "show" for a day, She had been married ten years, coitus was somewhat difficult, and she felt no desire. There was no vicarious menstruation. She was large in frame, but quite feminine in form; the breasts and mons veneris well-developed. The vagina formed a blind sac, 2 inches deep. The uterus was apparently represented by an elastic body of the size of a broad bean, lying rather to the right. An ovary-like body occupied each labium majus. The pair were intensely tender to the touch, and caused great pain. They were, therefore, removed. A vertical incision was made in each labium. The right gland was easily detached, the left lay higher up, and was difficult to dissect away from its connections. The two excised organs were carefully examined under the microscope, and the appearances, as represented in lithographs, are published with Kochenburger's paper. They contained tubuli seminiferi and not Graafian follicles, and were distinctly testicles. There were vessels arranged like the spermatic and distinct cremasters but no vasa deferentia. Possibly, Kochenburger suggests, they existed, but were cut too close for recognition, at the operation. He refers to similar cases related by Hicco, Breisky, and others. The monstrosity is classed as hermaphroditismus transversus virilis.—*Br. Med. Jour.*

### Knots in the Umbilical Cord.

Lefour of Bordeaux (*Progres Medical*, July 8th, 1893) has made researches in this subject. A knot in the cord is very likely to kill the fœtus by offering a simple mechanical obstacle to the circulation; the umbilical vessels become plugged owing to changes in their coats. In one case, where the fœtal movements and heart sounds ceased twelve days before delivery, there was a tight knot in the middle of the cord. Arteritis and complete obstruction by organized clots were detected on examining the vessels at the affected point. Lefour experimented by injecting water at constant pressure into the umbilical vessels, and found that the knot does not markedly impede circulation unless there be compression as well. An amount of pressure which would hardly be dangerous in a cord free from knots is perilous when a knot exists. In the absence of compression a knot, even if tight, probably loosens itself under the increased pressure of the contractions of the fœtal heart.

### Absence of Genitals; Vicarious Epistaxis.

Kochenburger (*Zeitschr. f. Geburtsch. u. Gynak.*, vol. xxvi, pt. 1, 1893, p. 72) examined last year a patient aged 16. She had never menstruated, but for three years had been subject to severe epistaxis every fourth week. She had been married a week, and coitus was found impossible. The patient was in general development, distinctly feminine, there was a little hair along the linea alba. The mammæ and mons veneris were well developed. There was a slight fold in the vestibule, which was very shallow; there was no fossa between the labia minora. The patient was put under chloroform, and no vagina could be detected. In its place lay a cord-like structure which ran upwards for an inch and a half, ending in a fold which ran transversely and clearly represented Muller's ducts; no trace of ovary could be found. Kussmaul stated over twenty years ago that evidence derived from examination of a living subject only is of no great value in these cases. Kochenburger insists, however, that since Kussmaul's days bimanual palpatation has been carried to such perfection that definite evidence can be obtained from the live subject. He feels sure that the ovaries were absent in his case, yet vicarious menstruation, in the form of epistaxis, occurred regularly. This contradicts Kussmaul's theory that menstruation, and even the molimen, is always absent when the vagina and uterus are undeveloped, though the ovaries may be present and contain follicles.—*Br. Med. Jour.*

## ARMY AND NAVY.

U. S. ARMY, FROM OCTOBER, 1, 2893, TO OCTOBER, 7, 1893.

By direction of the Secretary of War, leave of absence for three months, is granted Captain William D. Crosby, Assistant Surgeon.

Majors Alfred A. Woodhull and Alfred C. Girard, Surgeons, are detailed as delegates to represent the Medical Department of the Army at the annual meeting of the American Public Health Association to be held at Chicago, Illinois, from the 9th to the 14th of October, 1893.

Norman Seaton, Asst. Surgeon. To proceed to New York, N. Y., for temporary duty, August 18, 1893. To proceed to Jersey City, N. J. for temporary duty, September 3, 1893. To rejoin station September 9, 1893.

Sprague, E. K., Asst. Surg. To proceed to Cairo, Ill. for temporary duty, Aug. 26, 1893.

Vol. LXIX, No. 17.
Whole No. 1913.

**Phenacetine-Bayer**

ANTIPYRETIC and ANALGESIC; Prompt, safe and effective in Fever, Influenza, Rheumatism, Neuralgia, Pneumonia, Cephalalgia and all forms of pain.

Phenacetine is given in doses of 2½ to 10 grains, 3 or 4 times daily. It does not depress the heart.

Phenacetine is supplied in ounces, also in tablets and pills, alone and with Salophen, Sulfonal, etc.

**Sulfonal-Bayer**

HYPNOTIC and SEDATIVE; Indicated in all the Insomnias including those of insanity and the Neuroses; Causes no nervous or gastric disturbances. Must be given as directed.

The dose of Sulfonal varies from 15 to 45 grains; It should be given an hour or two before bedtime.

Sulfonal is supplied in ounces, tablets and pills; also in tablets in combination with Phenacetine.

*Other Farbenfabriken Products:*

**Salophen, Trional, Aristol, Losophan, Piperazine-Bayer, Europhen.**

## ORIGINAL ARTICLES.

### MEDICAL TREATMENT OF INEBRIETY.*

T. D. CROTHERS, M. D.†

The medical treatment of inebriety appears first in pictorial representations found in the ancient tombs of Egypt.

Here can be seen the states of stupor, nausea, vomiting, administration of drugs, showering by water, massage, flagellation and attempts to counteract the narcotism by external stimulation, also inunctions of the body, convalescence, and restoration, all faithfully outlined on these old tombs whose origin is lost in antiquity.

Fragmentary records of early Greek physicians contain references to the treatment of excessive wine drinkers.

The great philosopher and physician, Hippocrates, clearly recognized the disease of inebriety and left some very sensible rules of treatment.

From time to time, for the past twenty centuries, the question of the disease of inebriety and its treatment has come into prominence at intervals, then died away. Finally, at the close of the last century and the beginning of this, Dr. Rush of this country and several eminent European physicians affirmed the fact of disease, and laid down lines of treatment. But it was not until 1864 that the scientific treatment of inebriety became a practical reality, in the asylum at Binghamton, N. Y. From this time the rational study and treatment of inebriety begins.

Unlike other great medical topics, public sentiment has gone on in advance of scientific knowledge of this subject in its demands for means of treatment that shall control and cure the victim. In meantime, all rational study and treatment of inebriety has been obstructed by false theories and delusive misconceptions, that cling tenaciously as fogbanks along the shore.

Notwithstanding all the evidence, based on facts and experience, against the present methods of treatment, they still continue.

Temperance revivalists still boast of the number of pledged and converted as cured. As an evolution from this comes the empiric, with his secret specifics, boasting to have first affirmed the theory of disease, and claiming equally astonishing results with unknown drugs.

While the question of disease and treatment is passing through the period of renaissance, there are landmarks and clearly defined facts to guide all future studies.

Some of these outline facts grouped may help to clear away the errors that cloud the present conception of this subject.

The disease of inebriety, like other diseases of the brain and nervous system, follows a uniform movement, controlled by laws of dissolution, and conditions and causes that can be determined.

In the question of treatment, the first inquiry is, What is the present condition, the organic and functional derangements

† Superintendent Walnut Lodge Hospital, Hartford, Conn.

*Read before the Mississippi Valley Medical Association, October 5, 1893.

of the brain and nervous system, also nutrition and digestion?

Second: What are the special effects of alcohol on the nerves and brain?

Third: Is the use of spirits a symptom of other brain states? or is it an active factor in the causation?

Fourth: What neurosis and conditions of heredity are the active and latest factors in the history of the case?

From a study of these questions the lines of rational treatment will appear. Take a common case as an illustration. You are called to a case of gastritis. The man has drunk spirits for a long time and taken but little food; both digestion and nutrition are seriously impaired. Alcohol has affected the sensory and motor nerves, it has made the brain unstable, and lessened power of control, with evident hyperæmia. If the treatment is based on these symptoms alone but little can be expected. If we go back and find that the use of spirits began after some severe strain or state of exhaustion, or following as an entailment of some disease or traumatism, either physical or psychical, or originated in contagious surroundings and faulty conditions of living, new lines of treatment are indicated. If further inquiry shows a neurotic inheritance, direct as from alcoholic ancestors, or indirect as from insane, consumptive, epileptic, or any other neurosis, new indications appear.

The treatment of a case which checks the brain and nerve irritation by narcotics and, by the withdrawal of spirits and the use of eliminatives relieves the functional disturbances, is only partial. If at this period the pledge or conversion fills the mind by auto-suggestion with confidence that cure has taken place, or if the system is kept saturated with narcotics until the dominant idea of cure prevails or the mind is buoyed up on the delusive hope of final and permanent cure, the results are accidental and uncertain. Should final restoration follow the use of these means, the real causes of cure are unknown and belong to the realm of psychotherapeutics. Cases which recover after these psychical remedies are those in which the drink craze or symptom dies out or becomes exhausted, through the operation of inherent forces, and not by the last means or remedies used.

The medical treatment of inebriety must depend on the causes and conditions of the case. Without this knowledge all remedies are empirical. From such a clinical knowledge the physician may point out the lines from which a return to health may be expected. He can foresee the oncoming insanity of which the drink impulse is a clear symptom; or the paresis with this stage of exaltation and spirit excess; the acute delirium, the melancholia, the masked epilepsy in the dipsomaniac, and many other conditions that can be anticipated and studied. Many of these cases, in which to a superficial observer only the drink symptom is prominent, are found to have a uniform line of progress and termination. Take a hundred cases of inebriety and from a careful study of heredity, present condition, and the action of alcohol, etc., etc., a prognosis can be made that will be verified in ninety per cent. of all cases. The first question to be determined in a given case is the physical condition of the patient. As a rule all inebriates suffer from degrees of paralysis, both vaso-motor, sensory, and functional. Sub-acute inflammations and reflex irritations are common. The heart's action is variable, and the organ is enlarged. The liver is also enlarged and frequently the seat of low grade of inflammation. The stomach also suffers from both organic and functional derangements. Neurites are very common and of all degrees, usually called alcoholic rheumatisms and neuralgias. These are only the most general and prominent symptoms and call for general eliminative treatment. There is present in all these cases defective elimination of waste matter, also chemical changes of both cell and tissue, due in part to the direct action of alcohol and its indirect action on the nervous mechanism. As a result ptomaine poisonings, new soils for the growth of bacteria, also new centers of congestion and irritations occur. The bath corrects these indications by stimulating the cutaneous surface. Hot air baths or hot water baths, with rubbing once or twice a day, are the first essentials in treatment. Following this should be given what is termed internal lavage, or washing based on the same principle. This is best secured by saline and mercurial cathartics, with copious draughts of warm or acid waters. The patient should be placed in conditions where a certain

amount of control over his habits and conduct can be obtained. Either at home, under the charge of a trusted nurse, or in an institution where all the surroundings can be guarded.

All spirits should be removed at once, and a careful watch of the case be maintained to ascertain any organic or other diseases which may be masked by the use of spirits. Epilepsy, tuberculosis, paresis, hysteria, and other affections often come into great prominence when spirits are abandoned. The remedies most valuable following the removal of spirits and baths are the cinchonia bark infusions, nux-vomica preparations, together with the bromides, codeia, sulfonal, and other narcotics for the control of the nervous irritations. Strychnia is inferior to nux-vomica in my practice. Choral is unsafe and uncertain in many cases. All narcotics should be given in large doses for a short time and changed frequently and discontinued. Beef tea, hot milk, hot acid drinks, are often very effectual as narcotics, allaying nervous irritation. Rest and frequent massage with the baths, mild tonics, salines, and good foods are often all the means essential for restoration. In many cases the drink craze disappears from the use of these means alone. In a certain number of cases the origin of the drink symptoms is associated with syphilis and bad living, or the advent of syphilis has been followed by excessive use of spirits. In these cases mercury, arsenic, and the iodides should enter very prominently into the treatment. In a certain number of cases unusual states of stupor and delirium follow each other with explosive violence, unusual to ordinary alcoholic intoxication. A suspicion of specific poison followed by mercurial treatment gives the strongest confirmatory evidence in the good results from such means.

When inebriety is traceable to head injuries, from blows, heat, shocks, sudden emotional strains, etc., etc., sub-acute inflammation and degenerative cell and functional changes present are noted in the impulsive exhaustive drink symptoms. Both the prognosis and treatment should anticipate grave brain troubles.

Direct heredity, noted by inebriate ancestors, demands in the treatment total change of life and long periods of brain and nerve rest. Where the heredity is indirect, coming from allied states of brain degeneration, such as insane, idiotic, criminal, pauper, epileptic, and other profound brain diseases, the medication should be directed to lessen and favor return to states of health. In some of these cases the action of spirits varies widely. The insanity of the drink symptoms and the organic degeneration is so pronounced as to suggest various causes. These are the cases which become drug-takers of all kinds, and the cure or subsidencr of one drug addiction is followed by another. These are the cases which appear in every community as shining examples of cure by "gold specifics," by prayer and pledge, and who very often secretly use opium or other narcotic drugs.

The hysterical confidence in permanent cure by unknown measures in a brief time is always open to grave suspicion of hysterical credulity or duplicity.

In neurotic cases where alcohol is quickly followed by intoxication, especially in young persons, a grave prognosis is present. The treatment should be a radical change of life and also include all the constitutional remedies found valuable, such as baths, tonics, foods, and mineral drugs.

In cases where cell and brain exhaustion from imperfect rest and food are present, the treatment must be nutrient and hygienic, rather than by drugs. Dyspepsia and the various disturbances of the stomach and liver, which are relieved by spirits concealed in bitters, are always grave troubles. Faulty or no mental control and unstable brain equilibrium, with its irregularities and exhaustion in inebriety require long persistent treatment. Many of these neurotic cases are benefited by mental treatment. There is a realm of psycho-therapeutics in which the medical man can foster dominant ideas and direct the activities of the brain along hygienic lines of living. Hypnotism has been tried in this way with indifferent success, so far. New surroundings, with change of thought and impulse, have been very patent in some cases. A primary condition in all these cases is exhaustion of the central brain structure. In most cases full restoration never occurs. The drink craze dies out, but the weakness and lowered vitality remain. In periodic cases the explosive character of the brain energy accumulating and discharging at

intervals suggests a line of treatment which will afford an outlet for this abnormality. In some cases restraint by drugs at the period of discharge is valuable ; in others baths, exercise, cathartics seem to divert the energies and relieve the paroxysm. In one case a prolonged hot air bath, with severe massage, avails ; in another, a long tramp in the country, with dog and gun, and severe exercise ; in another, cessation of all work and rest in bed, assisted with bromides ; another case abstains from food at this period, and in other cases eats to excess for two or three days, and thus avoids the paroxysm.

Various measures to control the drink paroxysm in these cases will depend on a study of the case. The premonitory symptoms are often very clear, and means of prevention can be provided. Where the case is in an asylum the application of means are more positive, but when the case is not under control greater skill is required. Many of these periodic cases drink only on holidays, or days of general rejoicing. If they can be carried over these periods they remain sober until similar occasions recur again. For many years I treated a case who never drank except during the holidays. A week before the approach of this season he was given mineral waters, nux-vomica, bromides at night, severe exercise and hot baths, with sharp rubbing, every day. This was continued for two or three weeks, then discontinued, and the drink craze was averted. In one case a man never drank except when on the seacoast ; change of residence to the mountains was followed by perfect abstinence. States of contagion are very patent causes in some cases, and when recognized can be remedied. A form of hypnotic influence prevails, in which men drink to excess in certain surroundings and in certain company, and abstain where conditions are removed. Asylum care and study reveal many very curious facts along this line. Often pronounced cures follow from a careful study and recognition of these symptoms. The tendency to epilepsy, suicide, dementia, and other grave diseases should always be considered in such cases, and both local and constitutional remedies be persistently applied.

The continuous drinker, either in moderation or excess, has always the strong possibility of paresis, dementia, and cerebral hemorrhage before him. The continuous action of spirits is that of a paralyzant, disturbing and breaking up all the chemical and vital processes, either slowly or rapidly. The condition to be treated, after the removal of the active or apparent causes, is that of brain anæmia and profound central exhaustion, and degeneration of all the vital processes.

Institutional care and treatment of these cases are obviously the most important and practical. In the near future, when the disease of these cases is recognized, their early treatment at home by the family physician may be practical. His knowledge of the family history and surroundings will enable him to apply preventive means and measures that are impractical later on.

Public sentiment permits these cases to grow up in every community under the impression that all excess of spirits is simply moral weakness, within control of the victim. Thus, the period of curability is passed, and only when the disease and insanity of the victim is unmistakable are rational means applied. In an experience of seventeen years in asylums for these cases, I have rarely seen recent cases of inebriety coming for treatment. As a rule, all persons admitted to asylums are those who have exhausted every other means for relief, and who have used spirits until both the brain and organism are obviously diseased. To expect cure or permanent restoration in a few weeks from any form of treatment in such cases is impossible, or cure even from long medical care in any very large number of cases cannot be reasonably expected. Yet, the most reliable statistics show that fully thirty per cent. are restored from institutional medical care extending over ten or twelve months. I am sustained by the best authorities in asserting that the inebriate is more curable than the insane, but the treatment must be based on his actual condition and extend over a long period of time, and be founded on general principles of rest and organic restoration.

The restraint and care of an asylum is of more value for its control of the surroundings, and the facility for the application of exact methods of treatment, than for its removal and restraint from alcohol. Rest and building up of brain and nerve tissue takes away the demand for alcohol

more positively than locks and barred doors.

The central object of all treatment is to remove the causes which demand spirits for relief. To silence this craze for alcohol is not curative any more than the narcotism of opium removes the cause of pain.

While the use of alcohol will create general organic degeneration, the demand for its use is always symptomatic of grave central irritations and lesions.

Locks and bars, pledges, chemical restraint by drugs, appeals to diseased higher brain sections, appeals to the credulity and disordered senses and emotions by "gold cures," or specifics, are all empirical. Yet, excepting imprisonment in jail, all these measures claim to be curative, and refer to examples whose conditions can be explained by other and more rational causes. The drink symptom is in many cases self limited and will change and disappear as a natural dissolution process, sometimes merging into organic disease of the stomach, heart, liver, kidneys, nerves, and brain. Cerebral hemorrhages, organic diseases of the lungs, kidneys, and nerves are very common entailments following the excessive use of spirits. The examples of cure by specifics or moral means are as a rule diseased, and the change of the drink symptom is followed by other concealed or pronounced organic lesions. The breaking up of the drink craze by narcotics and other powerful drugs will of necessity increase the degeneration, and directly predispose to insanity.

Another central object of all treatment is to restore the organism so that the narcotic effect of alcohol or other drugs will not be demanded. This is a brief outline of some of the more prominent facts in the treatment of inebriety. It will be evident that we have scarcely touched the subject. Only in the most general way have the real facts and principles of treatment been recognized. The noise and confusion of empirics and specific vaunters are only foam bubbles on the surface, whose only significance is the agitation and movement that presages the oncoming truth. No question of practical medicine appeals more strongly to physicians in every community for solution. What shall we do with the inebriates is answered to-day by quacks, pietists, politicians, and reformed inebriates. The mystery, credulity, and dogmatism of their answers is "confusion worse confounded."

From scientific studies by medical men the correct answer must come. They are the real teachers of the nature and treatment of inebriety, and yet to-day nearly half a million politicians, empirics, reformers, clergy, temperance men, and reformed inebriates are talking, writing, and teaching what inebriety is and how to cure it, and not a single score of physicians in this country have given the subject any study. What a startling reflection this is on medical science and medical men. Some of the facts which may be considered as starting points in the study and treatment may be outlined as follows:

The treatment of inebriety extends far back to antiquity. Public sentiment is to-day far in advance of any real knowledge of the nature and treatment of inebriety; hence, the armies of specific vaunters and temperance revivalists who claim such remarkable results. The disease of inebriety, like all other diseases, follows a uniform line of events, from certain special causes and conditions. Its treatment must begin from a knowledge of the present condition of the case and the effects of alcohol on the system; how far the use of alcohol is the symptom of other diseases and what heredity and neurosis enter into the case. A study of these and other conditions point out the lines of rational treatment.

The prognosis and treatment depend altogether on a clear apprehension of the case. The first thing is to place the patient in the most favorable conditions for cure, where all the surroundings can be helpful, and the best means applied to build up and restore his brain and nervous system. This may be done in an institution or at home under the care of a nurse.

The withdrawal of spirits and the use of baths and massage daily, with brain rest, are essential. Remedies such as the bitter tonics, mineral salts and acids, nux-vomica, and often the bromides and the iodides are valuable. The use of nutrients, with rest and baths, fulfill most all the demands of each case. Reconstruction of cell and tissue is the object to be sought.

Specific poisons such as syphilis, or injuries to the head, starvation, and other conditions require special lines of medica-

tion. Heredity and all its allied neuroses are constitutional states of degeneration, to be treated on general principles; change of living and surroundings, with appropriate medication to build up the entire organism, must be applied in all cases.

Restraint, protection, liberty, and the application of means to meet all the demands and abnormalties must be applied.

The public treatment of the pauper inebriates must be in military hospitals, especially organized for this class. The treatment for those able to pay can be more completely carried out in special hospitals, which will combine all the best appliances of science to meet the wants of each one.

The entire subject must be studied from a higher level, and along the line of accurately observed facts.

---

No Mistake In The Pulse.—Dr. B— of Virginia is a very able man in two branches of human endeavor. He is famed as a physician, and as a consumer of wines at dinner he is probably not anywhere excelled. Because of the latter distinction he is rarely called upon professionally after dinner by those who know him. It happened not long ago, however, that the sudden illness of the wife of one of his friends made it necessary that he should be summoned in a professional capacity late in the evening. The doctor came, visited the patient, and prescribed.

As he was about to leave the house the sick woman's husband asked what the exact trouble was. The doctor put on a long face, and seemed unwilling to gratify the husband's curiosity; but finally, after much insistence upon the latter's part, he observed, gravely, that the lady had been indulging in too much strong drink but that he had prescribed, and that the ill effect would soon pass away.

The revelation astounded the husband, and he expressed some doubt as to the accuracy of Dr. B—'s diagnosis.

"I am not mistaken at all," he replied, indignantly. "I have had much experience in cases of this sort, and cannot be mistaken. The pulse is an absolutely accurate indicator. Mrs. S—'s pulse at this moment is the pulse of the inebriate." With this he left the house, not at all pleased that Mr.—S should have chosen to doubt his judgment.

Mr. S—immediately repaired to the sick room, and was still further disturbed on entering to find his wife in a most hilarious state of mind, laughing so heartily, in fact, that he was almost of the opinion that Dr. B—was right after all. Upon inquiring of madam as to the cause of her mirth, he was informed that Dr. B—had sat at her bedside, looked at her tongue, aud requested to feel her pulse. She had held out her hand, but the doctor had not taken it all, but had contented himself with placing the fingers of his right hand upon his own left wrist.

In short, the doctor had felt his own pulse.—*Harper's New Monthly Mag.*

Three Good Strokes.—An eminent New York divine, in the course of an address at a fraternity dinner recently, told this story. Said he: "I met a Brooklyn friend of mine a few days ago, and as he appeared to be feeling in an unusually exuberant frame of mind, I asked him why. He replied that he was happy because he had done three good actions the day before. He had met a poor woman on the street. The woman held a sickly-looking child in her arms, and she was weeping. Inquiry showed that she was weeping because she was convinced that her child was dying, and unbaptized.

"'But,' said the Brooklyn man, 'why do you not have the child baptized?'

"'Because I have no money, and the fee for baptism is one dollar,' said the woman.

"Whereupon the good Samaritan handed the woman a ten-dollar bill, gave his address so that she could bring back the change—which she did return—and went his way.

"That is one good action,' said the Doctor. 'Now for the other two.'

"'Oh,' observed the Brooklyn man, 'they are all three in that one. First, I relieved the sorrows of a weeping woman; second the child of eternal salvation; and third—' Here he hesitated.

"'Yes?' said the Doctor. 'What was the third?'

"'Well,' said the Brooklyn man, 'the third was that I got rid of that vile counterfeit ten-dollar bill I had been carrying for more than a year.'"—*Harper's Magazine.*

## ETIOLOGY AND PREVENTION OF DEAFNESS.*

GEO. F. KEIPER, A. M., M. D., LaFayette, Ind.

The writer submits herewith a table dealing with the reputed causes of the deafness of the pupils of deaf schools of nineteen states. This includes all pupils ever taught by these schools, excluding those for whose deafness no cause is assigned. The reports furnished are not scientifically correct. Some causes are recorded which are absurd. Effort has been made to eliminate these so far as possible. It is well nigh impossible to eliminate all. Until state institutions employ competent aurists so that the pupils may be properly examined, and until the reports of competent physicians can be obtained in preference to parent's, uncertainty will prevail, valuable information will be lost and hopes of prevention, based upon it, blasted. However, we hope to draw some lessons which we trust will stimulate further thought and investigation.

Our table deals with 9,897 cases; of these 3,559 were congenital in origin and from this we proceed to divide our list of causes into

I, Congenital,
II, Adventitious.

(*a*) Predisposing—
1, Age
2, Inflammations of upper air passages.

(*b*) Exciting—
1, Scarlet fever
2, Meningitis
3, Measles
4, Mumps
5, Catarrh
6, Typhoid fever
7, Scrofula
8, All others mentioned in table.

I, Congenital deafness is a fruitful source of study and investigation relative to its prevention. It is believed by many to be due to—

(*a*) Cousins intermarrying
(*b*) Persons congenitally deaf intermarrying.—This is on the same principle followed by breeders in securing peculiarities in stock.
(*c*) Relatives of deaf mutes marrying.

Therefore—

(*a*) Cousins should not marry.
(*b*) Persons congenitally deaf should not marry. Some fear a race of deaf mutes thus.
(*c*) Relatives of deaf mutes should not marry.

If a proper examination of these congenital cases were made the great probability is that they would, in a great measure, find their origin in *adventitious* causes which we now consider briefly:

II, Adventitious causes are either
(*a*) Predisposing, or
(*b*) Exciting.
(*a*) The predisposing causes are
1, Age
2, Inflammation of the upper air passages.

1, Age:—Deafness in the main originated in childhood. As far as possible the ages at which the children became deaf was ascertained.

*Read before the Miss. Valley Medical Association, Oct. 6, 1893.

The table shows that out of 5,514 cases, 4,011 became deaf before the age of 6 years.

[See tables on pages 630 and 631.]

2, Inflammations of the nose, pharynx, naso-pharynx and tonsils constitute, in the practice of aurists, the most frequent causes of deafness, our table to the contrary notwithstanding. From it we find catarrh and throat trouble to cause 266 cases or 2.7 per cent. This percentage is too low as all reputable aurists will readily admit.

In 1867, Drs. Roosa and Beard examined 296 cases of whom 200 has chronic pharyngitis and tonsillitis or nearly 68 per cent. It is indeed marvellous that owing to the remarkable prevalence of catarrhal troubles of the upper air passages, we do not have more deafness. I believe we may safely say that 70 per cent. of deafness among so-called deaf mutes may be directly attributed to diseases of the upper air passages and if they have received an amount of attention equal to that bestowed upon the diseases reputed to have caused the deafness, much trouble would be saved these unfortunates and some expense, the state.

Though the table be inaccurate yet when we take a summary of the deafness caused by the

(*b*) Exciting Causes
1, Scarlet fever
2, Cerebro-spinal meningitis
3, Measles
4, Mumps
5, Catarrh
6, Typhoid fever
7, Scrofula (syphilis?)
8, LaGrippe and
9, Throat troubles,

we may reason with some certainty.

These causes produced 2,393 cases or 24 per cent. Without the predisposing cause of inflammation of the upper air passages these exciting causes in a great measure would have been inefficient.

Some for argument's sake may say that these diseases produced trouble of the internal ear direct, without the intervention of catarrhal troubles to cause middle ear trouble. I reproduce from Dr. Spencer's article in the *Reference Handbook of the Medical Sciences*, a table comprising 4,102 cases upon this point.

| Reporter | No. of cases | Exter. Ear | Mid. Ear | Inter. Ear. |
|---|---|---|---|---|
| Blake | 1652 | 466 | 1128 | 58 |
| Burnett | 1187 | 279 | 868 | 40 |
| Spencer | 1263 | 243 | 978 | 42 |
| Totals | 4102 | 988 | 2974 | 140 |

The proportion of internal ear trouble is so small as not to require much consideration. Moreover the middle ear trouble may cause internal ear trouble.

Wines in making a compilation from the census of 1880 relative to deafness, finds out of 9206 cases, 4551 due to scarlet fever and meningitis alone.* In the table submitted we may regard errors present because the number assigned to scarlet fever and meningitis is too small.

PREVENTION.

The prevention of deafness demands first of all a removal of all predisposing causes. We have hinted at this partially in the previous discussion.

Concerning congenital deafness, if what has been asserted is true then the rules concerning marriage should be observed, legally, if not otherwise.

Catarrhal conditions of the upper air passages must be early relieved. In the main this requires surgical treatment, upon which a book might be written. However the principal causes to be removed are adeniod vegetations in the vault of the pharynx, and hypertrophic rhinitis and enlarged tonsils.

We have seen that the great majority of of the instructed contracted deafness before the age of six years. This excludes congenital cases. Whatever is to be done successfully must be done before the age of six years. Very much of the effort we put forth on these cases after the age of six is fruitless. Could aurists at the right time, put forth one fourth the effort they are called upon to do at an improper time, there would be better satisfaction on the part of physician and patient. There is nothing more unsatisfactory than treating an old case of deafness not due to necrosis of the ossicles. Chronic diseases mean inflammatory new tissue formation, which wherever it occurs is very difficult of removal.

A discussion of prevention so far as exciting causes are concerned would consume more time than would be justifiable. The watch word is prophyllaxis towards the infectious and contagious diseases. Of their skillful treatment you are all aware. Beware that the accompanying ear complications receive due notice and treatment.

## GALL-STONE COMPLICATED BY GASTRIC ULCER; AUTOPSY.

W. HENRY PRICE.

During the past summer while associated with Dr Phillip Marvel, of Atlantic City, a very interesting case presented itself, in which the differential diagnosis between gall-stones and hepatic cancer was rather more difficult than usual because of certain symptoms being absent, and on account of the patient having recently had his life insured, the autopsy involved more than a mere medical interest.

The history of the case is as follows: Benj. M., a colored man, fifty-one years of age employed in the Penna. R. R. yards, had been feeling badly for two months or more, and growing steadily worse, he called me in to see him on July 18, 1893.

By reason of the patient's ignorance accurate statements were difficult to obtain, but so far as the family history was concerned nothing could be elicited which bore upon the diagnosis of the case in question.

In regard to the previous history of the patient, he had enjoyed good health until about two months before my first visit, and had been doing hard work. He was temperate in all his habits.

His first symptoms of disturbed health were anorexia, general malaise and sense of great weakness. Then he became cognizant of a dull *constant* pain with tenderness in the region of the liver, and soon after he noticed that his stools were white, while the urine was black, as he expressed it. He however, kept at work and did not call in any regular physician, but contented himself by taking various patent medicines, now and then paying a single visit to first one doctor and then another, without diagnosis or relief.

Finally he became so weak that he was forced to take to his bed. At my first visit I found the conjunctiva and mucous membrane of the mouth deeply bile-stained, stools almost white and urine loaded with bile. He had lost flesh and strength progressively, and a physical examination revealed marked tenderness over the whole liver, although the organ was apparently not enlarged and no nodules could be felt.

The diagnosis of obstructive jaundice was made, with the possibility of a deep-seated malignant growth as its cause. Cancer was contemplated in view of the continuous loss of flesh and strength, the age and race of the man, the insidious onset, and, not least, the apparent absence of *paroxysmal* pain. Wishing to give the patient the benefit of the doubt, he was treated for catarrhal hepatitis by the administration of nitro-muriatic acid thrice daily, and potassium iodide in hot water between meals. Besides this, rest in bed, milk diet and the daily application of strong sinapisms over the painful area. After three days the stools became normal, urine was much lighter, conjunctivæ partially cleared up and the patient felt greatly better and highly gratified. Fractional doses of calomel were then ordered, which produced numerous loose stools and still further improvement in both subjective and objective symptoms, so that without permission he left his bed, went down stairs and took a walk. He soon realized that his ambition was greater than his strength, and was obliged to return to bed. This was followed by a return of all the symptoms, with clay-colored stools and signs of intestinal fermentation, no doubt from the absence of bile. The original treatment was resumed with the addition of capsules containing ox-gall to supply the necessary bile. Symptoms were again relieved except the tenderness and dull, constant pain, but he refused to take any nourishment because it distressed him. During this time fever had been more or less constant, the temperature rising as high as 102½°

The following day he began to spit mouthfuls of blood, and the next day he vomited about half a cupful of bright liquid blood. This was rather hard to explain and we were wont to ascribe it to venous stasis from portal congestion. Accordingly Rochelle salts was ordered taken before breakfast in hot water, with the idea of relieving the passive congestion. The laxative action of this brought away large clots of blood from the bowel which only served to make the case more obscure in its nature.

At this juncture the temperature fell

to 96½° which, of course, was explained by the internal hemorrhage. During the next two days more clots were passed per rectum and more blood was spat up, and he grew weaker and weaker and died in a semi-comatose state on August 14th, just four weeks after treatment was begun. For the last three days of life, the tenderness spread over the epigastric region and was so marked that palpation was impossible.

An autopsy was allowed because the insurance company, in an over-bearing manner, claimed that if cancer was the cause of death they would efuse to pay the money inasmuch as the patient had taken out his policy only three months before death, and in the nature of things the malignant growth must have been there before—a lame argument, as the risk had been accepted. However, as the case turned out to be gall stone, the money was paid without murmur.

On opening the body the abdominal organs and tissues were found deeply bile-stained, and about one quart of ascites present. Liver not enlarged and surface smooth. Strangely enough the gall-bladder was not distended but its left side was adherent to the anterior aspect of the stomach near the pylorus, and when this adhesion was carefully separated a small perforation was noted through this double wall, through which the bile had escaped into the stomach and thus prevented its accumulation in the gall-bladder. Perihepatitis had caused the liver to be tightly adherent to the diaphragm, and the stomach and several coils of small intestine were covered with inflammatory lymph. In the initial extremity of the common bile-duct, was tightly wedged a large spherical calculus, measuring three-fourths of an inch in diameter and weighing forty-five grains. No other stones were found. Upon opening the stomach, which was also bile-stained, four clear-cut, irregular shaped ulcers were found involving the mucous and sub-mucous coats, and measuring about one-fourth to one-third of an inch in diameter, and at the base of two of these a small blood vessel was exposed which had ruptured and which evidently had been the source of the hemorrhages. At two other positions white spots were found which were evidently beginning ulcers also. The other organs were normal.

In reviewing this case, several points impress themselves upon us: first of all, the *constant* pain and tenderness, which were the misleading symptoms pointing toward malignancy, were no doubt due to the perihepatitis. The absence of *paroxysmal* pain may have been due to the fact that the gall-stone was so tightly wedged in that it made no new attempts to pass.

Then the very unusual perforation which took place from the gall-bladder into the stomach, was most interesting and accounted for the stools resuming their natural color, an effect we supposed to be the result of treatment at the time, but which was really only a coincidence, and misleading because it made us think there might be present only a simple catarrhal hepatitis, and contra-indicated operative procedure. The ulcers were, no doubt, secondary to the hepatic involvement, but were immediately responsible for the fatal termination of the case by hemorrhage. They were, in all probability, the result of a highly depraved nutrition, for the patient took practically no nourishment during the last three weeks of life.

---

Bacilli and Nitric Acid.—Bacteriologists have been for some time familiar with the fact that the common bacilli produce nitric acid and nitrite, but instead of seeking in these secretions the cause of the destructiveness of the microbes, they have directed their attention chiefly to the poisonous albuminous substances they have discovered in "cholera culture," but which prove to be the contents of the dead bacilli, and therefore perfectly harmless so far as the genesis of the disease is concerned. It is the active product of their vital function, and not any lifeless residium of decomposition and decay that works the mischief. By a series of experiments on rabbits, Profs. Esmerich and Tabor have shown in a Munich journal of the 10th of June, that the symptoms of cholera and of poisoning by nitrite are perfectly identical in their action on the blood, and on every part of the organism. These statements of the learned professors are undoubtedly correct, and in looking to the ptomaines for the deadly poison, there is opened a very important avenue for the therapeutic study of the disease.—*N. Y. Med. Times.*

## A CASE OF SENILE GANGRENE TREATED BY AMPUTATION.*

G. W. H. KEMPER, M. D., Muncie, Indiana.

The patient was Mr. A. W. C., farmer, native of Ohio, and aged 73 years.

In 1893, an attack of rheumatism began and continued for about one year,—nine months of the time being confined to his bed. Although never very strong, yet he had led an active, stirring life. He had been a moderate drinker of alcoholic liquors. In the early part of the year 1891, he began to experience some pain in the left leg and foot. By the first of June, the pain was quite severe and accompanied with a sensation of chilliness. The pain gradually increased, and was described as stinging. He became quite a sufferer. About the first of September, he was removed from his home in Ohio to the residence of a daughter in Yorktown, near Muncie, and came under the professional care of Dr. Shively, of the former place.

About the 6th of September, a small, black spot appeared on the third toe of the left foot, and soon extended over the entire toe. At the same time the dorsum of the foot in the metatarsal region became reddened.

I first saw him on the 13th day of September, at which time the third toe was completely gangrenous. He was suffering a great deal of pain in the affected foot. It was evident that the arteries of the extremities were more or less atheromatous. His condition gradually and constantly grew worse and the quantity of opiates had to be increased in order to secure rest. Several circumscribed spots appeared over the leg and his general condition was not reassuring. The propriety of an amputation was discussed, and its chances were explained to the patient and his children. He decided to undergo amputation of the leg. I may add that an examination of the urine showed nothing abnormal.

On the 28th of September the gangrene had extended over the second and third toes and two inches upon the dorsum of the foot, and a well-marked line of demarcation was formed. The pulse was 92, temperature 100½°. At this date, assisted by Drs. Shively, Shields, Cowing and Coffin, I amputated the leg through the middle third, by the flap method. At the time, the discoloration on the leg had disappeared and the skin appeared healthy. Proper antiseptic precautions were observed,—ether being used as an anæsthetic. Upon making the section it was found that all the arteries were completely calcified, and not one was ligated. Two veins permitted more blood to escape than was desirable, and these were tied.

The operation was almost a bloodless one, and he soon rallied. He suffered considerable pain during the first twenty-four hours after the amputation, but never afterward except at dressings of the stump. He was supported by stimulants and generous diet.

The highest temperature reached was October 1st, when the thermometer registered 104°. He exhibited considerable delirium for a few days after the operation, and quite often somnolency was so profoundly marked that it required some effort to arouse him. He manifested quite a tendency to the Cheyne-Stokes respiration. On the third of October, about a tablespoonful of grumous pus escaped. From this time sloughing of the upper flap began, and continued until the tibia was exposed for a length of two inches. This portion of bone was soon denuded of its periosteum.

About one month after the amputation, the patient was seen by Dr. Marsee, of of Indianapolis, and, at his suggestion, we placed the stump in a tin splint, which contributed a great deal toward the immovableness of the tissues and aided granulation. The exposed bone gradually exfoliated and during the months of December and January was entirely separated. The soft tissues continued to throw out healthy granulations which slowly but gradually covered the extremity of the bone, and finally closed over the healthy skin, leaving a smooth and well-formed stump.

I saw the patient on the 17th of May, 1892, and found the stump in an excel-

* Read before the Miss. Valley Medical Association, October 5, 1893.

lent condition.* The circulation in the remaining foot and leg appeared to have improved since the removal of the diseased member. He was in an excellent state of health, but disposed to remain in the recumbent posture much of the time, because, as he remarked, "He had lain in bed so long that when he got up he ached and felt sore."

I have presented this case because of its clinical interest. A few points might be considered in connection with its study. The gangrene was due to the atheromatous degeneration of the arteries. The supply of blood to the extremity became less as the lumen of the arteries decreased by accumulated deposits upon their walls. Finally this supply was insufficient to nourish the extreme parts, and death necessarily followed. It was not associated with diabetes as many of these cases are.

Was amputation justifiable? I think the result of the case, although slow in process of healing, is a sufficient answer. While I am of the opinion that surgical measures were proper, I am inclined to think that we erred in not selecting a higher point of election for amputation. The red spots that were present on the leg early in the history of the disease, although absent at the time of the operation, indicated a low vitality of tissues unfitted for an ampntation.

Since I encountered this case, I have taken some pains to investigate the subject and note the observations of those who have had a more extended experience, and I feel that my researches may aid others,—hence I record them in connection with my solitary case.

Mr. Jonathan Hutchison was one of the first operators to call attention to the great value of high operations in senile gangrene.† He gives credit for earlier commendation of the operation to James.

The same month in which I operated, September, 1891, Heidenhain, of Germany, published a valuable paper based on twenty-five cases he had seen in the clinic of Küster, at the Augusta Hospital in Berlin.‡ These twenty-five patients underwent thirty primary amputations, three requiring double, and one a triple amputation. In ten of the subjects gangrene of the stump followed and secondary amputation was performed.

In a recent article,‖ Dr. Charles A. Powers has made an excellent summing up of these cases, and I quote his words: "Analyzing these cases, we find that four times, in circumscribed gangrene of the toe, Küster disarticulated, but that in every instance gangrene of the flaps occurred and extended to the foot. Lisfranc's amputation was secondarily carried out on one of these patients; he developed further gangrene and died of sepsis. A second was further amputated at the knee and again higher, the latter operation accomplishing cure. Both of the others were healed only after amputation through the femur. In three cases of primary amputation through Chopart's joint, the gangrene progressed in two and required femoral amputation. Primary amputation through the leg was employed six times: one case died from gangrene of the flaps and sepsis; three were saved by amputation through the thigh; the other two were healed after gangrene of the edges of the flaps and necrosis of the sawn surface of the bones. Of these thirteen low primary amputations, only two went on to healing, these in leg amputations; two patients died of gangrene of the flaps and sepsis; the remainder, nine, were saved by secondary amputation at or above the knee.

"Of the seventeen primary amputations through or above the knee-joint, nine were cured, while eight died of diabetic coma or heart weakness. Of the ten secondary amputations, all recovered. Separating, now, the diabetic from the non-diabetic cases, we find that of the eleven diabetic patients six were cured, while five died; and of the fourteen patients with simple senile gangrene, nine were cured, five dying. The fatal result was due to gangrene of the flaps and sepsis in two cases (one Lisfranc's amputation, one through the leg, both in the early days of antisepsis); in one case a man, aged eighty years, died at the end of nine days, from heart failure; one man, aged seventy-eight years, succumbed to hypostatic pneumonia; and another, aged fifty-two years, died at the end of nine days, with myocarditis, nephritis and ascites. The list shows that through the high amputation all patients were saved who were not severely afflicted with some general disease."

* He died of an acute disease in December, 1892.
† *Medico-Chirurgical Transactions*, Vol. 66, (1884).
‡ *Deutsche Medicinische Wochenschrift*, (1891).
‖ *American Journal Medical Sciences*, Nov., 1892.

In conclusion, I offer the following deductions:

1.—While the gangrene is confined to one or two toes, it is best to defer amputation. If the disease extends to the dorsum of the foot, amputation is proper.

2.—Amputation below the knee is rarely successful, owing to lack of proper blood supply and tendency to recurrence of gangrene in the stump.

3.—Amputation through the thigh will save a large per cent. of the cases, and especially so, when the subjects are free from a general disease. Mansell-Moullin observes that usually the thigh is small and wasted in the lower third; the artery is sound in Hunter's canal; the flaps are well supplied with blood; and old people, as a rule, resent operation very slightly; their tissues are not prone to inflammation.

4.—When amputation has been performed below the knee and gangrene appears in the stump, unless the patient is exhausted, it will be proper to perform a secondary amputation above the knee.

## AN UNUSUAL CASE OF HEMORRHAGE OF THE UTERUS.

CLARA T. DERCUM, M. D., Philadelphia.

The subject of these notes is an American girl of German parentage, aged twenty-six years, of a large well developed physique and by occupation a sales woman. Previous to this her present illness, she had always enjoyed perfect health. Her menstrual flow had without exception been normal in amount and duration, and it was only occasionally accompanied by a dysmenorrhœa which was scarcely sufficient to cause her any inconvenience. She menstruated normally in December, 1891, the flow beginning on the 24th of the month and continuing as usual for four days. Her next period, however, was delayed for nearly two weeks beyond the normal time, which was unusual in her case, not making its appearance until February 3rd, 1892. The flow was normal in character for four days. On the fifth day, however, instead of ceasing it became so profuse that from seven to eight napkins were required daily. As this condition continued for several days she finally sought medical advice.

Her history, which was obtained later, is briefly as follows: She had been gradually running down in general health for about one year and was undergoing a severe mental strain at the same time. This was in reference to breaking an engagement of marriage which she had come to regard as a very unwise one.

When she first consulted me on February 9th, I gave her a prescription containing hydrastis, ergot and dilute sulphuric acid, with the injunction that if the flow did not cease in a couple of days she was to remain at home. February 12th, she stated that the medicine had had no effect on the flow although she had remained at home for two days resting quietly. The mixture which she had been taking was continued with the addition of the deodorated tincture of opium, but as her stomach soon refused to tolerate it it was discontinued. Rectal suppositories containing one grain of opium and two and a half grains of ergot were substituted and administered every two hours. Her diet was non-stimulating, consisting chiefly of cold milk, luke warm broths and toast. In spite of this treatment the flow increased in severity. On the seventeenth of February a digital examination was made; the hymen was found intact so that the examining finger was only introduced with difficulty, the uterus was uniformly enlarged and flabby; the external os was so soft and patulous that the finger could be carried to the internal os without any trouble; the condition of the external genitalia as well as the entire absence of pain negatived the idea of an abortion, so that that as a factor in the causation of the hemorrhage could be safely excluded. Vaginal injections of water, from three to four gallons as hot as could be borne, were now given three times daily, a rubber tube attached to the bed pan carrying it to a bucket at the side of the bed.

The faradic current of quantity, one pole placed on the abdomen and the other

on the sacrum, was also used three times daily for periods of fifteen minutes. As this treatment was without avail in checking the flow of blood, another digital examination was made on the 21st., and the condition found unchanged. A bi-polar intra-uterine electrode was introduced two days in succession, and the faradic current of quantity used for fifteen minutes, this was followed by a bi-polar-vaginal electrode for the same length of time. This failed to stimulate the uterus to contraction as had been anticipated, the flow if anything increasing in quantity. Ergot and opium had been used continuously by the rectum during this period, one-thirtieth of a grain of strychnine together with the tincture of the chloride of iron had also been given three times daily.

On the 22nd, sixty-five grains of Squibbs extract of ergot were given hypodermically, this was repeated the following day. This also had no effect in diminishing the flow, which had now continued without intermission for twenty-one days, at times being profuse enough to saturate the bed. This steady drain had now reduced her from a healthy, robust looking girl to a physical wreck.

Realizing at last that if the flow continued at the same rate a few days longer the girl would die of exhaustion, I asked Dr. Eleanor C. Jones and Dr. F. X. Dercum to see her with me in consultation, which they accordingly did February 23rd.

After an examination as thorough as could be made without ether, we decided that the uterus was uniformly enlarged, but whether this was due to an excessive engorgement, or to some growth in the cavity, or to a rapidly growing intra-mural myoma could not be determined. On the morning of the 24th she was etherized with great care for we were afraid of heart clot in her then exsanguine condition. The sound passed three inches into the cavity of the uterus, which was now rapidly dilated, nothing abnormal being found either in its cavity or its walls. It was thoroughly curetted with a sharp curette and some hypertrophied mucous membrane removed. A solution consisting of two-thirds pure carbolic acid and one-third pure iodine was carried into the cavity on an applicator. The organ contracted on it with such force that its removal was only effected with difficulty.

Dr. Joseph Price examined her on the afternoon of the same day and stated that the uterus had contracted to its normal size. He had been called in to see her, for if we had not succeeded in checking the hemorrhage by the above procedure a gastro-hystorectomy would have been considered. Fortunately for the patient this was not required as the curetting and application of the solution above mentioned gave immediate relief, only a pale watery flow continuing for a few days.

A few weeks of complete rest in bed and a month at the sea-shore, together with mental quiet—for her engagement had been terminated—soon restored her to perfect health. During her convalescence iron and strychnine were freely used. Up to the present time her periods have been as formerly normal in amount and duration.

The obscurity of the etiology of the case is interesting, for why a young woman in apparently good health should be taken sick in this manner does certainly seem unexplainable.

Perhaps I may be open to criticism for not having resorted to more radical measures sooner, but there seemed to me in the beginning of her illness to be no special reasons for thinking that simpler measures would not effect a cure.

---

Fruit.—Fruit will destroy the desire for alcoholic drinks. Oranges and apples have been found to be the most effectual cure for inebriates, and the more they eat of these luscious fruits the more the desire for drink will diminish, until at last it is completely crucified, and so far as that individual is concerned, obliterated. —*The Vegeterian.*

---

How to Extinguish Fire.—Take twenty pounds of common salt and ten pounds of sal ammoniac (muriate of ammonia, to be had of any druggist), and dissolve in seven gallons of water. When dissolved, it can be bottled, and kept in each room in the house, to be used in an emergency. In case of a fire occurring, one or two bottles should be immediately thrown with force into the burning place so as to break them, the fire will certainly be extinguished. This is an exceedingly simple process and certainly worth a trial. *Med. World.*

# THE ANATOMY AND SURGICAL TREATMENT OF INGUINAL HERNIA AND ITS BETTER METHODS FOR CURE.*

HENRY O. MARCY, M. D., LL. D., Boston, Mass.

The radical cure of hernia is a subject at present which engages the attention of surgeons with much more than former interest. Quite a number of operators upon both sides of the Atlantic have reported long lists of cases operated upon with varying, but very large percentages of resultant cures. The advance made in this direction is based upon the well-known rules of aseptic surgery, which permit of free dissection, laying bare the parts involved which permits, as in no other way, a reconstruction of the abdominal wall and the replacement of the cord ; in a word, that the pressure from within the abdomen shall no longer be exercised in the direct axis of the opening. The work of Bassini in Italy, of Kocher in Switzerland, of Postkempsie in Russia, is quite parallel to and on the same line of research as that which pertains to a number of operators in our own country, notably Park of Buffalo, Bull and Cooley of New York, Fowler of Brooklyn, and Halsted of Baltimore.

The essential conditions for the restoration of the structures are agreed upon by all, namely : A free dissection in order that the cord may be lifted from its acquired pathological site, the canal restored in its obliquity, the internal ring closed from below upward closely upon the cord at its exit from the abdominal cavity, and the structures posterior to the canal reinforced and strengthened. Little by little this has been emphasized until now Halstead and Fowler have made the bold innovation of bringing the cord entirely external to the strong aponeurotic structures of the abdominal wall, to-wit : the fascia of the external oblique, making an entirely new canal for the spermatic cord. This innovation, however, is too recent to yet determine the full value of the procedure.

To Dr. Marcy is accredited the innovation of a free dissection, lifting the cord entirely from the canal and restoring the subjacent parts in a way to make the reformed canal at or near a right angle to the direction of the intra-abdominal pressure. He commenced his efforts in this connection more than twenty years ago, and in order to successfully accomplish the work believed it necessary to utilize sutures which could be buried in the tissues and there remain undisturbed. It seemed a ready inference that if animal ligatures could be applied to the larger arteries in order to produce their occlusion and yet remain without irritation or further disturbance of the parts, this should pertain also to the coaptation of the deeper structures of the body and their retention by a similar method. A series of histological studies upon the lower animals were undertaken by Dr. Marcy and the demonstration made complete that animal ligatures were more or less slowly absorbed and disappeared, leaving only a replacement of connective tissue structures at the site where they were imbedded. It was further demonstrated that this process varied very greatly ; that with silk the suture was encysted and oftentimes was made unirritating in a permanent way ; not seldom, however, such sutures became an irritant and they were slowly expelled by a process of proliferation, oftentimes after many months of localized pain, although the wound was entirely aseptic. This was true as a rule with silk-worm gut and silver wire. On the other hand, catgut, as ordinarily prepared, was untrustworthy by being absorbed too quickly and leaving the coaptated structures to yield before union had become firm. Chromicizing of the suture material after the manner of Professor Lister, however, renders the suture material much more resistant to the process of absorption, and as a consequence, makes it much more trustworthy. For many reasons, Dr. Marcy found that the tendon suture, as obtained from a considerable variety of animals, furnished a material of far greater value ; that from the tail of the kangaroo being quite superior to tendon obtained from any other source.

Dr. Marcy illustrated his lectrue by a series of slides, reproducing the magnifi-

* Abstract of an Address on Surgery, delivered before the general session of the Mississippi Valley Medical Association, October, 1893, at Indianapolis, Indiana.

cent illustrated work of the old masters—Kemper, Cooper, Scarpi, Bougerey, and others. By a general consensus of opinion the profession is indebted to Dr. Marcy as an innovator in this field of labor. He has established the value of the buried animal suture, and had published his results quite five years before the report of Weith of Germany, to whom in Europe the credit is generally attributed. The essential principles of his operation for hernia have become universally accepted. The results of the work of a large number of the modern operators give from 70 to 90 per cent. of permanent cures.

In résumé, Dr. Marcy claims that the peritoneal sac, as a rule, should be resected after suturing quite to its very base; that the deeper structures which go to make up the posterior wall of the inguinal ring should be reinforced and restored to their original normal condition; that the external wound should be closed without drainage and the skin wound sealed with iodoform collodion. In his large experience, involving several hundred cases, he states that where the intestine has not been involved from strangulation or other cause, not one of his patients has appeared to approach the danger line, and that of the entire number which he has been able to trace, more than 90 per cent. have remained after one year permanently cured.

## INVALID PENSIONERS AS LIFE INSURANCE RISKS.

H. T. GUSS, M. D., Washington, D. C.

An invalid pensioner may be a good and acceptable life insurance risk; and, conversely, a man who is a suitable subject for life insurance may be justly entitled to an invalid pension.

Much has been said lately in the way of adverse criticism and to make a comparison of the conditions appear ridiculous and reproachful to the veteran soldiers of our country.

But such statements and insinuations are reflections alike upon the veterans and the members of the medical profession as well, and are evidently made by those who are ignorant as to the qualifications of the applicants in either case.

The physicians of the country, in their varied functions as the medical examiners for the life insurance companies, as the examining surgeons for the United States pension office, and as the attending physicians of the applicants for insurance and the claimants for pension, are the responsible agents in all cases. All pensions are allowed upon the certificates of medical examinations or the medical testimony, more or less complete, filed as proof of the existence and continuance of disabilities, according to circumstances in each individual case. The exceptional cases not covered by this statement would not be over one or two per cent., and include those issued under service pension laws, etc. A thorough physical examination by a qualified physician is an invariable pre-requisite to life insurance.

Prominent physicians in many communities act as examiners for both insurance and pensions.

Whether the application is for insurance or pension or both, the physical examination and medical evidence will admit or reject the claim.

What is the condition and situation of a claimant for pension?

He desires that his physical disabilities shall all be noted, as the amount of his pension is largely determined by the extent and degree of disability from a certain cause or all causes. Like the patient in ordinary medical practice, he endeavors to describe fully and clearly the history and every detail of the disease or diseases of which he complains, and conceals nothing, so as to give the examiner a complete understanding of his condition. The examiner acts upon that which is reliable and confirmed by his examination. He has probably found some apparent evidences of disability from injury or disease or some functional disturbances, and recommends a pension.

Look now at the applicant for life insurance. He wishes to appear well and strong. He may declare he is in good health, and in all his personal and family history, without concealing any material facts he may be inclined to emphasize only those features which appear to him favorable to his case. He may or may not state that he is a pensioner or a claimant for pension. The medical ex-

aminer, having carefully gone over the formal application for insurance and reduced to writing a statement of certain facts relating to personal and family history as to health and disease, which is signed by the applicant and becomes a consideration of the contract, makes a thorough and complete physical examination. He finds the applicant without any apparent evidences of organic disease and recommends his insurance.

Supposing the same individual has been examined in each case, here is a paradox. The claimant for pension is disabled and pensionable; but, as an applicant for life insurance he is at the same time sound and insurable.

How is it? The liberal interpretation of "disabled" and "sound" at once renders the conditions much less antagonistic.

The insurance companies could not do business if they required a perfect physical development and condition and a faultless family and personal history, so few would be found eligible.

There is a general or average standard, but each case is passed upon its own merits. Every case has its individual equation, the several factors having different values and relations to be considered in their bearing on the particular case. In addition to the physical examination, the habits and occupation of the claimant are taken into account. Many companies, for example, will not insure men who are engaged in certain occupations, but may under certain conditions, insure one who has had a leg amputated at the knee if he is otherwise sound and whole.

Usually, the loss of a hand or foot or other lesser amputations the result of injury, the loss of an eye, total deafness of one ear, complete hernia not complicated, anchylosis of joints and permanent scars and deformities which are the result of gunshot wounds, and many other disabilities of a kindred nature, are not considered a bar to life insurance, but all of them would be pensionable.

Claimants are pensioned and justly entitled to pensions on account of these disabilities as well as for permanent evidences of rheumatism, chronic diarrhœa, malarial poisoning, the effects of scurvy and a host of conditions which may exist in a degree which almost every life insurance examiner would ignore in making his recommendation for insurance.

With regard to the question as to whether the applicant for life insurance is a pensioner or a claimant for pension, it may be noted that a careful examination of the special instructions to medical examiners recently issued by twenty-four of the most prominent life insurance companies of this country shows that only two of them direct attention to this point. In one of these, under the head of "questionable risks" are enumerated among others "persons who draw pensions on account of disease or present physical disability."

It might be presumed, from the fact that only two companies in twenty-four raise the question formally that it is regarded by them as a matter of little concern, but it must be remembered that the fact of an applicant being a pensioner will be brought out in nearly all cases in his statement made to the medical examiner, which, we have seen, is made a part of the contract.

Extended inquiry among personal friends and others who are drawing pensions has elicited the fact that quite a good percentage are insured and that in the majority of the cases the insurance was effected after the allowance of the pension and generally with a full knowledge of the fact and circumstances on the part of the insurance companies.

In the matter of pensions, our country has been very liberal, and its policy differs from that of most European powers in that pensions are confined almost exclusively to the military and naval service. "A pension is a gratuity and not a debt." It is held that the pension laws are beneficent in character and their interpretation should be broad and liberal. In cases appealed to the Secretary of the Interior it was decided that "an application for life insurance by a pensioner does not forfeit pension if disability still exists," and that a claimants' statement as to soundness is not a bar to pension."

From the foregoing it will be seen that the conditions are not incompatible. It should not, therefore, be considered that a pensioner must be an invalid or a physical wreck. The fact that a man receives a pension may be an important one to an insurance company—but merely as a fact. If its medical examiner finds him in good physical condition he can be insured and continue to draw a pension at the same time.

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316-18-20 North Broad Street,
PHILADELPHIA.

**TERMS**:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

**REMITTANCES** should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

**NOTICE TO CONTRIBUTORS**:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, OCTOBER 21, 1893.

## EDITORIAL.

### HARD TIMES AND FREE MEDICINE.

From every part of this great and rich country the news comes to us of extreme stringency in the financial position of our *confreres* the general practitioners. Never was there a richer opportunity for the masses to play the pauper than now. The present panicy state of the money-market affords people an immense excuse for wholesale imposition on the profession. The conditions of the times will not give them free bread, free clothes, free transportation on the railroads or rent free, but they hie away to many of our too numerous hospitals and dispensaries for free treatment—advice, medicine and all included for nothing, or for "ten cents"—the figure fixed in certain palatial infirmaries.

The consequence of all this has been most demoralizing to the profession and the public. Practitioners reduced to a state of enforced idleness and grim want, are forced either to quit their profession altogether, or to "meet *steal* with steel," to open rival dispensaries, to advertise, or to drift into down-right quackery.

Many cases have come to our knowledge which go to prove that the practice in vogue in many of our largest dispensaries is a species of downright robbery and tends to work incalculable harm to the profession. Case after case is taken from among people of ample means and turned over to the hospital or to the college professor for his clinic, without a word being asked as to their mendicity or ability to pay anything at all. Cheap railroad excursion rates drain the outlying villages for miles in every direction.

This hydra-headed monster of indiscriminate free treatment must be siezed and strangled or we will soon see the profession of medicine dragged in the dust; open downright quackery will be rampant and integrity and honor in the healing art will be things of the past.

By no means let us withold our services to the poor and deserving, for humanity

compels us to gratuitously attend those without means. Nor let us strip the field of such clinical material as legitimately belongs to the teacher, but let the teacher not forget that he has no prescriptive right to filch from the struggling practitioner what justly belongs to *him*.

## BACTERIOLOGICAL NOTES.

### WATER FILTRATION AND CHOLERA.

Koch (*Zeitschrift f. Hygiene und Infectiuas krank heiten*, XIV 1893), brings out a large number of interesting facts concerning the relation of water supply to cholera. The statements in this article conform to the results which the author has heretofore obtained in his investigations of cholera and its prevention. The recent (1892) epidemic of cholera in Hamburg has furnished the opportunity for Koch to verify his theories concerning the relation of drinking-water and the transmission of cholera and typhoid fever. The importance of this subject in its practical application to our own water supplies renders a somewhat careful consideration of this article very desirable. The experiences of Hamburg, Altona and Wandsbeck are exceedingly instructive. These three cities which are adjacent to each other form practically one city excepting their water supplies are separate. Wandsbeck is supplied with filtered water from a lake which is not exposed to contaminating conditions ; Hamburg gets its water from the river Elbe above the city, it uses the water in an unfiltered condition ; and Altona is supplied with filtered water taken from the river below the city.

The points to be observed are, that while Hamburg was frightfully stricken with cholera, Altona and Wandsbeck were practically free from it. It is of further interest to consider that Hamburg took its water from a point in the river where its contamination was slight while Altona drew its supply from the river after it had received the sewage of 800,000 people. The line of demarcation was very striking. On one street which for a long distance forms the boundary, the Hamburg side was badly infected with the disease while the Altona side remained free from it. Still more singular is the fact, that one group of houses on the Hamburg side which were supplied with water from the Altona side remained uninfected.

Koch attributes the comparative freedom of Altona to the filtration of its water. Four-fifths of the cases which did occur in Altona were traced to an infection in Hamburg. The experiences of the present year, however, have shown that a filter bed of itself is not sufficient protection. The bed must be complete in every particular and the filtration must be conducted in the most thorough and painstaking manner and with frequent bacteriological examinations for a control on the filter. Epidemics of typhoid fever in Altona have demonstrated the existence of a connection between the disease and imperfect filtration. [The observation and results will cause the Pettenkofer school some trouble to answer or explain. —Ed].

---

"Giving the Quilt."—The Queen, says *Hearth and Home*, is an expert and indefatigable knitter. During the Egyptian campaign she and the ladies of the Household employed themselves in knitting quilts, which, at the end of the war, were sent to Netley Hospital for the use of the wounded. One of these, made entirely by her Majesty, and bearing an elaborate V. R. in the centre, was the coverlet *par excellence* of the institution, and in universal demand for a time. In assessing the claims of the candidates for the honor of sleeping under it, the medical staff naturally gave the precedence to the most severely wounded, and as the most severely wounded was the one most likely to die, very soon, alas ! an evil omen attached itself to the distinction, the climax of which was reached one night, when a poor soldier, feeling some one touching his bedclothes, woke up with the perspiration pouring down his face, and cried out, "Oh, sir, do anything you like with me, but for God's sake don't give me the quilt !"

# TRANSLATIONS.

## PSEUDO-MEMBRANEUSE ENTERITIS AND ITS ROLE IN GYNECOLGY.*

In the *Annales de la Policlinique de Bordeaux,* May, 1893, Monod remarks that he has frequently noticed in women who are suffering from uterine disease the existence of intestinal symptoms characterized by colic more or less acute and by the discharge of membranous debris with the stools. At times the patients have noticed this phenomenon themselves, but usually they have only taken notice of it after an interrogation which has directed their attention to this special point. The relative frequency of this clinical observation has induced Monad to suspect that perhaps there exists between the uterine symptoms and the intestinal symptoms more than a simple coincidence. Pseudo-membranous enteritis considered as a morbid entity has provoked during recent years a certain number of interesting works where this affection is described as a distinct variety of enteritis, or more precisely, of chronic colitis. Van Swieten, Fernel, Woodward in America, and many others among whom may be mentioned Professor Potain, have insisted upon this special form of chronic inflammation of the mucosa of the large intestine, which may be readily recognized by the quite distinctive character of the products expelled with the stools. At times these are simply slimy or with filaments of a glutinous appearance ; at times the patients expel veritable membranous ribbons which may present a length of 30 or 40 centimeters and which closely resemble often the debris of tapeworms. From this comes the various names which have been given to this disease, *glairous*, *dry, glutinous*, *pseudo-membranous colitis*. The authors have noticed the coincidence of this affection with hysteria and the neuroses. They have likewise called attention to the frequency of habitual constipation in the patients so afflicted. In certain cases the intensity of the pains added to the gravity of the general state of the patients has given rise to the error of diagnosis of ascribing the condition to the probable existence of cancer of the intestine. In 1888, Monad presented to the Society of Anatomy of Bordeaux the false membranes passed in large quantities by a woman 47 years of age, who was subject to very acute painful crises and who was considerably emaciated, and who had been treated by her physician as suffering from intestinal carcinoma. She was suffering, however, only from membraneous entero-colitis which was eventually cured. But if the clinical history of chronic colitis is to-day well recognized, the authors seem to be but little preoccupied in searching for the links which may bind this condition to an affection of the uterus or of its appendages. Monad has searched in vain in the classical treatises upon gynecology for any mention of pseudo-membraneous enteritis in the cortege of symptoms which accompany diseases of the internal genital organs of the woman. The characteristic clinical manifestations are as follows :

The *pain*, a nearly constant symptom, located most often towards the middle of the abdomen, in the region corresponding to the transverse colon. It may be localized in the right iliac fossa at the level of the cæcum. A characteristic feature of this pain is its intermittent and paroxysmal nature; the periods of crisis may vary between some days and several months; it may occur every month synchronously with the menses.

An habitual symptom of this form of colitis is the *constipation.* The authors have insisted upon the tenacity of this constipation which resists all the measures employed to combat it. Finally, in all of the patients there exist nervous manifestations in varying degrees. The patients are always very impressionable, offering the attributes of the most confirmed neuropathic state.

The *anatomo-pathologic characteristics* of the products eliminated by the intestines have been well recognized. At times there are thickened mucosities, which surround the fecal matter and adhere to them. More often there are veritable isolated membranes, very resistant, having the appearance of elongated rib-

* Translated for THE MEDICAL AND SURGICAL REPORTER by W. A. N. Dorland, M. D.

bons or of placques or else gathered together in the form of fibrous bundles. The chemical and histological examination of these products shows, whatever may be their appearance, that they are always nearly entirely composed of mucous.

As regards the treatment of this condition, an affection so irregular in its course and of which the nature is so poorly recognized. it is plain to see that therapeutics is almost disarmed. The choice of an alimentary régime can not be along precise rules. Most of the patients have found that the use of milk was the only possible aliment during the period of acute crisis. Alkaline mineral waters have seemed to be truly efficacious. To these should be added intestinal antiseptics in the form of naphthol or salol. The principal indication is to combat the constipation. For this purpose the oily purgatives are to be preferred. To the same end daily lavements, either simple or boracized, should be administered. Recently lavage of the intestine with an alkaline solution, through a long rectal canula has been proposed in the treatment of membraneous colitis. This is a way which seems rational. When the pains are very acute, the applications of revulsives upon the abdominal wall in the form of tincture of iodine or of repeated vesications, may have good results. In the wealthy clientele one should advise a thermal cure at Vichy, Vals or Plombières; for those patients who are particularly nervous, Néris should be preferred.

As to the relation existing between this membraneous colitis and affections of the genital tract, it is worthy of notice that pseudo-membraneous enteritis is much more frequent in the woman than in man, and these women show deviations in the position of the uterus with or without inflammatory exudations around the pelvic viscera.

## HERNIA OF THE VERMIFORM APPENDIX.*

Dr. A. Brieger, Breslau, the author, considers only the cases which contain only the vermiform appendix in the hernial sac. The origin of such hernia can be classed under two heads, the same as all other hernia; namely congenital and acquired. First form is usually found to be caused by the adhesion of the vermiform appendix with the testicle during fetal life. A second cause, of equal importance, which may form during early fetal life, is the patulous condition of the tunica vaginalis; which may act as a channel through which may pass an appendix of abnormal length. Other predisposing causes are, a long mesentery to the appendix and displacement downward of the cœcum.

The author reports six cases of irreducible hernia of the vermiform appendix, the last having occurred at the surgical clinic of Breslau. He further describes eighteen cases of incarcerated hernia of the vermiform appendix, the last one a case also belonging to the above named clinic. He adds two cases in which the hernial sac contained the appendix and a portion of the omentum.

The author concludes his article as a result of his observations:

1. That herniæ of the vermiform appendix are of more frequent occurrence than is generally known.

2. It is impossible to make an accurate diagnosis of such hernia. When symptoms of incarceration occur, hernia may be considered in connection with the right inguinal or femoral hernia.

3. There is always an important point to remember, which is that the vermiform appendix frequently undergoes pathological changes which produce often marked complications.

4. These cases, even if irreducible, require early operations owing to the fact of complications arising from the appendix.

5. The operation, with few exceptions, consists in resection with accurate closure of the lumen, after the method of Mikulicz. Reduction can only be practiced in such cases where the appendix is normal. —*Arch. f. Klin. Chir.*, 1893

* Translated for The Medical and Surgical Reporter by Marie B. Werner, M. D.

### Gonorrhœa Occurring in Little Girls.*

Dr. Cassell, the author, has examined the discharge of pus from the genitals of thirty small girls and found gonococci in twenty-four. The youngest of these was seven months and the eldest eleven years. In the greater number of cases the author

was able to trace the infection to other members of the family. Dr. Cassell does not favor the idea that all these cases were infected by direct means, but believes that this class of people living in close quarters, may contaminate each other by means of bed linen, sponges or body linen.

The diagnosis is of importance. In all cases of gonorrhœal vulvo-vaginitis there was free discharge, and thick, creamy, greenish-yellow pus.

Therapeutically, the author treats the patients by local and general baths, placing the pelvis high for local injections, for which he uses an ear syringe containing 1 to 2000 of sublimate solution daily.

If the discharge becomes less profuse after two or three weeks he uses, two to three times weekly, a one to a one and a-half per cent. solution of nitrate of silver; these are continued until the cure is established, which usually occurs between two and three months.—*Berlin Klin. Wochen.*

# ABSTRACTS.

## A CONTRIBUTION TO THE HISTORY OF THE DISCOVERY OF MODERN SURGICAL ANÆSTHESIA, WITH SOME NEW DATA RELATIVE TO THE WORK OF DR. CRAWFORD W. LONG.*

LUTHER B. GRANDY, M. D., Atlanta, Ga.

The true story of the first discovery of anæsthesia, and of the circumstances connected therewith, has not yet been told in print. Reliable history is never written by the generation which make it. The generation which inaugurated the era of painless surgery has passed away; the participants in the long and bitter controversy over the question of priority have disappeared; and those of us who have since come upon the scene may now undertake to gather up the data relating to that great discovery, unaffected by favor and unbiased by prejudice.

In 1839, Velpeau, of Paris, described the attempts to find some agent capable of preventing pain in surgical operations as nothing less than chimerical; and in 1846, Sir Benjamin Brodie, of London, said: "Physicians and surgeons have been looking in vain, from the days of Hippocrates down to the present time, for the means of allaying or preventing bodily pain." Yet four years and a half before that statement was made, surgical auæsthesia, under the influence of ether, had become a demonstrated fact in a Georgia village, in the hands of Dr. Crawford W. Long. The claims of Dr. Long to the honor of this discovery have been presented to the world by no less a champion than the distinguished J. Marion Sims himself. Dr. Sims' article appeared in the *Virginia Medical Monthly* May, 1877; but it was hurriedly prepared on the eve of the author's departure for Europe, after an imperfect correspondence with Dr. Long and others, and contains some errors which the latter was anxious to have corrected. Upon these errors the claim has been raised that to another belongs a large part of the credit which the profession has accorded to Dr. Long.

My own interest in this matter is due to an accident, which need not be related here. For the purposes of this paper I have been kindly furnished by the Long family with all the documents, correspondence, and certificates which had been gathered by Dr. Long in support of his claim to priority. I have had access to papers which Dr. Sims never saw. I have talked with some persons, and corresponded with others, who were personally acquainted with Long and his work in 1842, and am thus able to present some features of the case hitherto unpublished.

The paper of Dr. Sims had its origin in an interview with Dr. P. A. Wilhite, of Anderson, S. C., October, 1876.† Dr. Wilhite was witnessing one of Dr. Sims' operations in New York, and remarked that he "assisted at the first operation

* From the *Virginia Medical Monthly*, October, 1893.

† Dr. Wilhite died in the early part of this year. I heard of his death, for the first time, after this paper was begun.

ever performed under the influence of ether." He then said that this operation was done by Dr. C. W. Long, of Jefferson, Ga., in March, 1842, while the patient was completely anæsthetized with sulphuric ether. He "presumed that he (Wilhite) was the first person who ever profoundly etherized any one," and then related how he had playfully and unintentionally etherized a negro boy to the point of complete anæsthesia in the fall of 1839, near Athens, Ga. Sims' article makes it appear that four young men—Wilhite Groves, and two Longs (relatives of Dr. Long)—were medical students in the office of Dr. Long prior to the events of 1842, and the author states that Wilhite's story about the negro boy encouraged Long in his belief that ether might be used for surgical purposes. These statements of Sims', based entirely upon information received from Wilhite himself, have caused the friends of the latter to manify his relation with this matter, and even to enter a claim in his behalf.*

As a matter of fact, Wilhite did not become a student of Dr. Long in his office until the latter had done several operations under ether. After graduating at the University of Pennsylvania, in 1839, Dr. Long spent one year in New York city, and returned to Jefferson, Ga., to practice medicine in the summer of 1840. It is not likely that he would have attracted four students to his office at the age of twenty-five. He had no students under him until after his marriage, August, 1842, and the first was his cousin, Dr. J. Long. In another place in Sims' paper, Wilhite is made to say that he assisted Dr. Long in operations "under the influence of ether in 1843 and '44, while he was a student in Dr. Long's office." Wilhite was not even present at Dr. Long's first operations. In the entire volume of papers before me relating to Long's first two or three operations, including the sworn statements of parties who were actually present, no mention is anywhere made of Wilhite. Moreover, not until years afterward does it seem to have occurred to Wilhite himself that he had any connection whatever with the discovery of anæsthesia. When Dr. Long's case was being argued before Congress, he obtained from Wilhite a certificate (Feb. 4th, 1854,) with these words: "I entered the office of Dr. C. W. Long, of Jefferson, Ga., in October, 1844, where I continued about eighteen months. Not long after I entered his office, and not later than 1845, I heard the said Dr. Long speak of having used sulphuric ether by inhalation, to prevent pain in surgical operations, he referring to a period of time before I entered his office." The remainder of the certificate states that he (Wilhite) had heard others speak of the operations, and he was under the impression that he had himself talked with the first patient upon whom an operation had been done. Between this certificate and the story as related to Sims, twenty-three years later, there seems to be an irreconcilable conflict.

Up to the time of Dr. Long's death, the relations between himself and Dr. Wilhite appear to have been very friendly. In his interview with Dr. Sims, in 1876, Wilhite said that "Long was the real and original discoverer of anæsthesia, and believed he would be so acknowledged if all the facts in the case were fully set forth." When Sims was in correspondence with both of them during the preparation of his paper, Wilhite wrote Long:

ANDERSON, S. C., Jan. 16, 1877.

"*Dr. C. W. Long*:

"Dear Doctor.—I have just received a letter from Dr. J. Marion Sims, of New York, stating that you will not write to him, or at least that he wrote to you about three weeks ago and had received no reply. If you don't do so soon it will be too late. He has been preparing an article for publication, and wants to place you right before the world. You have been apprised, I suppose, of the nature of the article. Why you have been connected with, and will be the leading spirit in, the article, happened in this way: While I was in New York last summer at one of Dr. Sims' private operations, several prominent physicians being present, I happened to remark that I witnessed the first or second operation ever performed under an anæsthetic. Every one said that I was mistaken, and particularly Dr. Sims. * * * After that I met Sims at his office and gave him such particulars as I could recollect of your first operation, and also urged your claims to the priority.

* See *Transaction of South Carolina Medical Associations*, April, 1893, and also "History ot Surgery in South Carolina," by Dr. E. F. Parker, *North Carolina Medical Journal*, June, 1893.

He at once wrote you on the subject, and has since become very much interested in the matter.

"Now, Doctor, it is but justice to you, as it is due the world, that you give Dr. Sims such information as he asks for at once, as he is going to all this trouble only to place the proper credit of this great discovery on the man who justly deserves it. I earnestly hope you will comply with the doctors request as soon as possible. As I have been the means of giving the investigation of this subject its present shape, I am exceedingly anxious that you give all the information you can, that you may, and justly too, receive the credit of this great discovery. If you will act, it will certainly be so. Dr. Sims also wants a short history of your life, which don't fail to give.

"Hoping to hear from you, I remain yours, etc.

"P. A. WILHITE."

In reply to this, Long reminded Wilhite that he did not witness the operations, as stated, and asked him to send Sims a certificate similar in character to the one above quoted. Dr. Wilhite replied:

ANDERSON, S. C., Jan. 27th, 1877.

"*Dr. C. W. Long:*

"Dear Doctor.—Yours of the 22nd is at hand, and I have also just received a letter from Dr. Sims, which I will answer to-day. In regard to the certificate you spoke about, it will not be necesary, I think, as Dr. Sims has my statement written out in full. He was very particular to get all the points and facts I could recollect. In my statement *I did make a mistake about my being present at the first or second operation, which mistake I will correct.* (Italics mine—L. B. G.)

"If you still think proper, I will send a certificate. Let me know and I will give you any assistance in this great matter.

"Yours truly,

"P. A. WILHITE."

Sims' article appeared in May, 1877, and Long at once noticed the errors and the absence of the promised corrections. He requested Sims to correct the mistakes, but the latter replied that the "misplacement of a few names and dates would not alter the main facts in the case." He sailed for Europe in a few days, and the matter was dropped.

The above is sufficient to show, beyond the shadow of a doubt, that Dr. Long was the "real and original" discoverer of the anæsthetic properties of ether, *and that he could not have received any assistance or suggestions whatever from young Wilhite.*

It is not material to the strength of Dr. Long's case whether the negro boy incident ever happened or not. However, there is no evidence to show that he knew anything of it until nearly forty years after it is said to have occurred. I have lately had an interview with Miss Fannie Long, to whom Dr. Long had often told and retold the circumstances relating to his discovery. In his later years she became thoroughly familiar with every detail of her father's claim, and at his death he confided to her keeping all the documentary evidence in his case. She tells me that the above story was related to Dr. Long by Dr. Wilhite himself, in the presence of several of the family, when Wilhite was on a visit to her father's house in the spring of 1877. After hearing it, Dr. Long replied: "Doctor, this is the first time I ever heard of it."

There is living near this city an old gentleman, who still preserves a clear recollection of the events of that period, and to him I am indebted for the following letter.

EDGEWOOD, DEKALB COUNTY, GA., June 27th, 1893.

"*Dr. L. B. Grandy*:

"Dear Doctor.—In response to your inquiries, I will state that I was intimately acquainted with Dr. C. W. Long, and was frequently with him after he located in Jefferson, Ga., in the summer of 1840. He often administered the vapor of ether to us young men of the village for the exhilirating effect produced, and he told me that he became acquainted with this property of ether while a medical student in Philadelphia. Upon one occasion, in the fall of 1841, I think, he remarked to me that he thought ether could be used to prevent pain in surgical operations, and that he intended to make the trial at his earliest opportunity. I moved to Athens January 20th, 1842, and introduced the inhalation of ether among the young men in that place. Before this time the practice of thus taking ether was unknown in that section. At

Dr. Long's request, I sent him some ether from Athens in the winter of 1842. Shortly afterward he came to Athens, and told me that he had operated successfully under the influence of the ether.

"These are the facts as I now remember them. Up to the time that I moved from Jefferson, Dr. Long did not have any students in his office. If ether had been employed in sport in the neighborhood of Athens previous to my introduction of it there, I never heard of it. In reaching the conclusion that ether might be used in surgery, I do not think Dr. Long received any outside assistance. In my opinion, the idea was original with him.

"Yours, very truly,

"R. H. GOODMAN."

The circumstances which led to Dr. Long's first operation are thus described by himself, in a letter to Hon. D. L. Swain, LL. D., June 4th, 1866.*

"In December, 1841, a company of young men were in my office, and requested me to prepare some nitrous-oxide gas for inhalation. I informed them that I did not have the necessary apparatus for making it, but that I had an article which would produce like exhilerating effects, and which I considered equally safe. They expressed a desire to inhale it, and it was administered that night to most of the company. They were so well pleased with the effects that it soon became fashionable to inhale the ether, and I noticed persons while under its influence receive injuries which were sufficient to produce pain, but on inquiring of them if they suffered any pain, they uniformly told me that they had not. I noticed one young man receive an injury of the ankle-joint, which disabled him for several days, and he informed me that he did not feel the slightest pain until the effects of the ether had passed off. Observing these facts, I was led to believe that surgical operations might be performed without pain, and proposed to the gentleman on whom my first operation was done that if he would submit to the operation while etherized, I would charge nothing, or only a nominal fee, for operating."

This operation was for the removal of a tumor from the neck of James M. Venable, March 30th, 1842. A second tumor was removed from the same patient June 6th following.† The last clause in the above letter will explain the following entry in Dr. Long's ledger.

JAMES VENABLE.

| 1842. | |
|---|---|
| Jan. 28th. Sulphuric ether | $ 25 |
| March 30th. Ether and excising tumor | 2 00 |
| May 13th. Sulphuric ether | 25 |
| June 6th. Excising tumor | 2 00 |

The details of that first operation under ether have been published by both Dr. Long and Dr. Sims. Concerning the subsequent operations, not much need be said.

On *July* 3, 1842, Dr. Long amputated the toe of a negro boy for disease.

On *September* 9, 1843, he extirpated a tumor from the head of Mary Vincent, of Jackson, Ga.

On *January* 8, 1845, he amputated two fingers of a negro boy. The certificates of two witnesses to this operation state that the first finger was removed under the anæsthetic, and that the boy experienced no pain; that the second was removed without ether, and was very painful. It occurs to me that Dr. Long's conduct in this case proceeded either from the fear of keeping the patient under the anesthetic too long, or from a desire to test the action of the ether. The latter view is made plausable from a statement of Long lower down.

If Dr. Long had promptly made public the results of his work, American medicine would have been spared the most tragically interesting chapter in this history. But, under the circumstances, he pursued a course both natural and commendable, and his reasons, as given by himself, were entirely cogent. He knew that he was the first to make the discovery, and he anticipated no controversy. His operations had all been of a minor character, and he only waited for an opportunity to test his anesthetic in capital surgery. But cases of heroic surgery were not common in those days in the practice of a young physician, in a thinly settled community one hundred and thirty miles from the nearest railroad. As far as it went, his work was well known in the small sphere in which he moved. Before me are several certificates—three of them

* Dr. Swain was the uncle of Dr. Long's wife, and at the time of this letter was President of the Uninersity of North Carolina.

† These operations were done in the presence of Jas. E. Hayes, A. T. Thurmond, W. H. Thurmond, E. S. Rawls, afterwards a practicing physician, and perhaps others. Certificates of these gentlemen are before me, besides also those of Venable's family.—L. B. G.

from physicians who were prominent in that section at that time—to the effect that "Dr. Long's operations were public and notorious in and near Jefferson, Jackson county, in the year 1842;" that he "made no attempt to conceal the character of the article inhaled, nor made any request that the results of his operations be kept secret."

Dr. Long's delay in going into print with his cases is thus explained by himself:*

"I was anxious, before making my publication, to try etherization in a sufficient number of cases to fully satisfy my mind that anæsthesia was produced by the ether, and was not the effect of the imagination, or owing to any peculiar insusceptibility to pain in the persons experimented on. At the time I was experimenting with ether, there were physicians high in authority, and of justly distinguished character, who were the advocate of mesmerism, and recommended the induction of the mesmeric state as adequate to prevent pain in surgical operations.† Nothwithstanding thus sanctioned, I was an unbeliever in the science, and of the opinion that if the mesmeric state could be produced at all, it was only in those of 'strong imaginations and weak minds,' and was to be ascribed solely to the workings of the patient's imagination. Entertaining this opinion, I was the more particular in my experiments in etherization."

In the meantime, Wells and Jackson and Morton were at work. With some assistance from one another, they arrived successively at the anæsthetic properties of nitrous oxide gas and sulphuric ether; and Morton, with an eye single to glory and business, secured a patent on ether under the name of *Letheon*. In the Massachusetts General Hospital, Boston, October 16, 1846, Morton admisistered his "letheon" to a patient for Dr. J. C. Warren, and a tumor of the neck was successfully removed. Other operations followed in quick succesion by the hospital staff. They were described in the *Boston Medical and Surgical Journal*, November, 1846, by Dr. Henry J. Bigelow. October 27th, 1846, Jackson and Morton published their letters patent, announcing the discovery of "letheon" as an anæsthetic; but their "letheon" was nothing more nor less than sulphuric ether.

Now began the celebrated "Ether Controversy," which I will pass over rapidly. Wells claimed the honor for himself, but having failed, both at home and abroad, to receive the recognition he sought, he ended his life by suicide Jan. 14, 1848.

When Dr. Long saw that he was anticipated in the matter of publication, he began at once to collect the evidence in proof of his own work. He obtained the affidavits of those operated upon, with dates, the sworn statements of witnesses and of those who knew of the operations, and his first article appeared, with some of these certificates, in the *Southern Medical and Surgical Journal* (Augusta, Ga), Dec., 1849.

In 1852, a bill was introduced in Congress to purchase Morton's patent for $100,000. This was opposed by Dr. Charles T. Jackson and the friends of Wells. Dr. Long's claims were also presented, and Sims says they were formidable enough to block the movements of Morton to get the appropriation. In 1854, Jackson made a visit to Long in Athens, and having satisfied himself as to the latter's priority in the use of ether, proposed to him (Long) to lay their claims conjointly before Congress as the real discoverers of anæsthesia. At the interview between them, Judge Andrews, of Madison, Ga., was present by Dr. Long's request. Dr. Long declined all of Jackson's suggestions, and instructed Senator Dawson, of Georgia, to make no compromise, but to place his claims solely on their merits. The matter drifted along with true congressional slowness until it was finally lost in the preparations for war. Morton was greatly disappointed at not receiving the reward from Congress. In New York, July 15, 1868, having fretted himself into a congestion of the brain, he drove furiously up Broadway and leaped from his buggy near Central Park. He was taken up insensible and carried to St. Luke's Hospital, where he died an hour later. It was not long before Jackson was committed to an asylum, hope-

* Extract from an unpublished (?) paper read before the Medical Society of Georgia, April, 1853.

† Dr. Long here refers probably to Dr. Gibbs, of South Carolina, who, at that time, was especially prominent among the class of physicians above alluded to. He, and others, claimed to have "witnessed operations on patients mesmerized and declare that mesmerism was the *ne plus ultra* needed to kill pain in surgical operations."—L. B. G.

lessly insane. After some years of confinement, he died, August 28, 1880.

The ether controversy was never reopened. Dr. Long continued to practice in Athens, and enjoyed a good patronage. Of course he regretted not having received the recognition he was sure he deserved, but his life was not saddened thereby. In regard to his discovery of anæsthesia, he had often said, "My only wish about it is to be regarded as a benefactor of my race." While on a visit to a patient June 15, 1878, he was stricken with paralysis, and, without gaining consciousness, died the next day. The Georgia Legislature has agreed to place his statue in the National Gallery of Statues in Washington. Dr. Long combined excellently the noblest qualities of the physician with the highest attributes of the gentleman. He knew that the credit of the discovery was properly his; but through all the long controversy he was content to rest his claims on their merits alone, and conducted his case with dignity and honor. He claimed nothing for himself that was not his; his character was known of all men, and was above reproach; he was modest, honest and truthful to the last degree; and he "kept the covenant of his heart's true life till his days were numbered."

Paul found in his travels many altars erected to as many gods, and in Athens another, "To the Unknown God." So the tourist can see, in Hartford, Conn., a bronze statue erected to the memory of Horace Wells; in Mt. Auburn Cemetery, Boston, a marble shaft to W. T. G. Morton; in Paris, a life-size marble statue of Crawford W. Long; and in Boston, a monument of white marble dedicated "To the Discoverer of Anæsthesia." It bears no name, but to one familiar with history it recalls the sad story of hopes that were disappointed, ambitions that were defeated, and lives that were lost, through their connection with the most humane and beneficent discovery of modern times.

Only one word more. Dr. Long's priority in the use of ether is beyond question. His discovery was the logical outcome of certain observed phenomena, and he proceeded to develop it in a scientific way in order to make assurance doubly sure. In the meantime, others less philanthropic gave a patented name to a common article, and, in some haste, announced a great "invention," which, later, they tried to sell for money. But, thanks to Dr. Sims' clear presentation of the evidence, the medical profession generally, I believe, have recognized the precedence of Dr Long's discovery.

It is a little surprising, therefore, that the author of a popular text-book on surgery should say, "I hope I may be pardoned for saying that the evidence in Dr. Long's favor seems to me quite inconclusive." I hope I may be pardoned for reminding him that the blindest persons *are those who will not see.*

A late writer in the *Medical Record* (Jan. 7, 1893) has read history to such little purpose as actually to state that Dr. Long himself never claimed to have "demonstrated painless surgery by etherization." Will the gentleman from New England kindly tell us, what was Dr. Long's object in going before Congress with his case when he saw that others were claiming the credit of the discovery? He might also explain Dr. Long's refusal to accept Dr. Jackson's proposition, and his instructions to Senator Dawson, above referred to.

People, and especially the inhabitants of those cities and sections where new discoveries make late impressions, part with their long-cherished opinions with great reluctance, and then only when the evidence becomes such as to convince the most unwilling. The present instance will be no exception. It is only to be expected, therefore, that there will remain some persons whose understandings will not be enlightened.

---

The Reading Doctor.—The best informed and most successful physicians are those who read the greatest number of medical journals for, in this way, a comparatively small amount of reading suffices to keep them conversant with current medical news and at a trifling cost.

---

Removing Odors From the Hands.—A paste of ground mustard and water is a first-rate agent for removing traces of disagreeable smelling substances from the hands, such as salts of valerianic acid, cod-liver oil, etc. Huber claims that any oily seeds when powdered will answer this purpose. The smell of carbolic acid may be removed by rubbing with dampened flaxseed meal.

## THE ACTION AND SAFETY OF CHLOROFORM.

H. A. Hare, M. D., and E. Q. Thornton, M. D., present the following summary of the results of their investigations on the subject.

From a careful study of the experiments so far reported, from studies made by one of us two years ago with H. C. Wood, and finally from this careful series of experiments we believe that the subject can be settled by the acceptance of both views in a modified form, or in other words that there is no real antagonism in the beliefs that chloroform kills by depression of the respiration or paralysis of the heart. We very positively assert that chloroform practically always kills by failure of respiration when administered by inhalation, provided, and this provision is most important, that the heart of the anesthetized is healthy and has not been rendered functionally incompetent by fright or violent struggles or, again, by marked asphyxia. By a healthy heart we mean one which has not undergone true fatty degeneration or has not so severe a valvular lesion as to make the slightest variation in the even tenor of the circulation fatal.

As positively as we assert that chloroform kills primarily by respiratory failure, so do we also assert that in excessive dose by inhalation it has a depressant effect on the circulation which is chiefly due to centric vasomotor, depression with final depression of the muscle itself. Depression of the cardiac muscle alone is never great enough to cause death when the chloroform is given by inhalation, but we believe that gradual asphyxia with the direct depression of the circulation may do much towards producing a fatal result, for vasomotor integrity is almost as necessary to life as an intact cardiac mechanism. This circulatory depression has been considered a safeguard because it was supposed to prevent chloroform going to the vital centers, but in reality it is no safeguard because profound circulatory depression is as great an evil as respiratory narcosis. That the circulatory depression may be dangerous is not only evident, but it is stated to be so by the Hyderabad Commission itself at the end of paragraph No. 8. This circulatory depression may be so profound that recovery is impossible, even with the most thorough artificial respiration a fact stated by the second Hyderabad Commission in paragraph 25, which we quote in this paper. This emphasizes the fact that we can not afford to totally ignore the effect of chloroform on the circulation and we can not consider the patient in danger of circulatory failure *only* when the respiration *ceases, but as soon as it becomes abnormal.* On the other hand, we should remember that even if chloroform has been given properly, the arterial pressure may be so low as to give no pulse in the radial artery and yet the circulatory system be ready to respond at once when the drug is removed. If, therefore, the chloroform is properly administered is there danger of its circulatory effect in man? We think that it is just at this point that our research and every other research on animals fails and necessarily fails, to produce a positive reply. The variation in the action of a drug on a diseased individual from its effect on the normal one is notorious, and we have no right to dogmatically assert that there is absolutely no danger of a circulatory depression in man, even if we found no evidence of failure in dogs, because there may be many idiosyncrasies or variations through disease in the human being which may completely reverse the results of experiments on healthy animals.

In other words, supposing that the amount of depression from very full doses of chloroform equals 25 units this amounts to little in the normal heart, but if the heart be depressed 25 additional units by disease the depression of 50 units may be fatal, particularly if to this 50 is added 25 units more of depression through fright and cardiac engorgement through disordered respiration or struggling. That true depression of the heart muscle may take place under chloroform seems to us most undoubted and we think that the tracings in every research that we have seen support this view. There is always a decrease in cardiac power manifested by the decrease in the force of the individual pulse beat and this passes away only if chloroform is removed early enough. We also agree with McWilliams that from the very first inhalation of chloroform there is a constant tendency to cardiac dilatation.

We come finally to all the important questions :

1.—Is chloroform a safe anesthetic ?

2.—Are we to watch the pulse or respiration during the use of the drug, and what are the signs in the respiratory function indicative of danger to the patient ?

3.—What is the true cause of death from chloroform ?

4. Is death from chloroform possible when it is properly administered ?

5. Under what circumstances is the surgeon to use chloroform in preference to the less dangerous anæsthetic, ether?

6. What is the best way of administering chloroform ?

To the first question the answer is yes, for the majority of cases, provided it is given by one who is skilled in its use and not only knows how to give it but to detect signs of danger. It is not as safe as ether at any time, other things being equal, and never safe in the hands of a tyro.

To the second question the answer is, watch the respiration, *because as soon as enough chloroform is used to endanger the circulation the respiration will show some signs of abnormality either in depth, shallowness or irregularity.* In other words, the very effect of the drug may be to cause such deep and rapid respirations that an excessive quantity of the drug is taken into the lungs and continues to be absorbed even after the inhaler is withdrawn.

As there is always a fall in pressure under chloroform it is difficult to feel the radial or temporal pulse and the respiratory center recognizes the degree of arterial depression, which its sister vasomotor center has permitted by finding that its blood supply is insufficient. As respiration fails first it should be watched first. Finally, it is only by watching the respiration that we can tell how much chloroform the patient is getting. We do not watch this function for danger alone but to tell us of the dose.

The answer to question three is that death is always due in healthy animals to respiratory failure accompanied by circulatory depression, which latter may be severe enough to cause death even if artificial respiration is used skilfully. Death only occurs in the healthy animal when chloroform is given in excessive quantities.

Question four is impossible to answer for man from the basis of experimentation, as we can not produce identical diseased states in animals with those developed under various conditions in man. The physician having a case of heart disease should always advise the patient of the danger of any anæsthetic and he should remember, whether it is wise to tell the patient or not, that anæsthesia always means a step toward death even in the healthiest of men. In the event of a death under chloroform the physician is not to blame if he has taken proper preliminary precautions and given the chloroform properly.

Every one is agreed that the patient taking chloroform should have plenty of fresh air, and in India we understand that to all intents and purposes patients are operated on in the open air, at least as compared to the closed rooms necessary in America and Europe. This free supply of air is important, whether we believe death to be imminent from cardiac or respiratory failure, but this supply of air matters little to the patient if he does not breathe freely nor does the dose of chloroform amount to aught if it is not drawn into the chest. The dose of chloroform is not the amount in the inhaler but the amount taken into the chest and finally the amount absorbed by the blood vessels. The rapidity and depth of respiratory movements is therefore, as Lawrie asserts, the entire key to the situation. We watch a windmill over a well to see if it is pumping into a reservoir a given quantity of water. If the windmill works irregularly so that we know its pumping action is deranged we separate it from the pump until the wind blows steadily, in order that it may pump regularly. Similarly we withdraw chloroform, as Lawrie says, whenever respiration becomes disturbed in rhythm or when struggling disturbs it, because it is the first indication that the drug's action is uncertain and because there is no telling the dose which is absorbed. While watching the respiration will not warn us of a sudden cardiac arrest in fatty heart plus chloroform depression, neither will the pulse give us such warning and we are confident that the statement of the Hyderabad Commission that the *respiration should be watched is correct,* for we believe from a long series of observations that gradual cardiac failure never occurs

without producing respiratory changes from the very first. In other words, we do not believe that in a healthy heart chloroform can cause serious disorder without as a result of beginning disorder disturbing respiration and, second, that in a healthy heart a quantity of chloroform sufficient to disorder it will by its direct action disorder the respiration. If, as an extra precaution, one assistant watches the pulse while the other watches the respiration, very well; for though the respiration is the more important function the man watching the pulse might discover an irregularity which the anæsthetizer may not see reproduced in the respiratory action, but as divided attention generally means a slighting of both objects in view Lawrie is right in insisting on the pulse being let alone.

In answer to question five we have several points to offer: 1. Hot climates where ether is applicable and where a free circulation of air increases the safety of the patient; 2. Chloroform may be used whenever a large number of persons are to be rapidly anæsthetized so that the surgeons may pass on to others and save a majority of lives, even if the drug endangers a few, as on the battlefield where only a small bulk of anæsthetics can be carried; 3. Its employment is indicated in cases of Bright's disease requiring the surgeon's attention, owing to the fact that anæsthesia may be obtained with so little chloroform that the kidneys are not irritated, whereas, ether, because of the large quantity necessarily used, would irritate these organs. Quantity for quantity, ether is, of course, the less irritating of the two; 4. In cases of aneurism, or great atheroma of the blood vessels, where the shock of an operation without anæsthesia would be a greater danger than the use of the anæsthetic, chloroform is to be employed, since the great struggles caused by ether and the stimulating effect which it has on the circulation and blood pressure might cause vascular rupture; 5. In children or adults who already have bronchitis, or who are known to bear ether badly or in other words, have an idiosyncrasy to that drug, chloroform may be employed; 6. Persons who struggle violently and who are robust and strong are in greater danger from the use of chloroform than the sickly and weak, probably because the struggles strain the heart and tend to dilate its walls.

The safest method of administration is by Lawrie's or Esmarch's inhaler because these provide free circulation of air and do not distract the attention of the anæsthetizer from the respiratory movement by complicated apparatus. Apparatus much like these in allowing a free amount of air, are the Hyderabad chloroform inhaler, or open-ended cone with Krohne and Seseman's respiration indicator attachment. The Junker inhaler, even with its modifications, is too complicated and cumbersome and while less chloroform is wasted in administering the drug it must all be thrown out of the bottle afterwards. If used at all it should be used with the increased air supply and respiration indicator of Krohne and Seseman.

We agree so heartily with Lawrie's conclusions that we print them below:

1. The chloroform should be given on absorbent cotton stitched in an open cone or cap. (A depression made through the opening in the inside flannel bag will answer as well.)

2. To insure regular breathing, the patient lying down with everything loose about the neck, heart and abdomen, should be made to blow into the cone, held at a little distance from the face. The right distance throughout the inhalation is the nearest which does not cause struggling or choking or holding of the breath. Provided no choking or holding of the breath occurs, the cap should gradually be brought nearer to, and eventually may be held close over the mouth and nose as insensibility deepens.

2. The administrator's sole object while producing anesthesia is to keep the breathing regular. As long as the breathing is regular and the patient is not compelled to gasp in chloroform at an abnormal rate there is absolutely no danger whatever in pushing the anesthetic till full anesthesia is produced.

4. Irregularity of the breathing is generally caused by insufficient air, which makes the patient struggle or choke or hold his breath. There is little or no tendency to either of those untoward events if given with the chloroform. If they do occur the cap must be removed, and the patient must be allowed to take a breath of fresh air before the administration is proceeded with.

5. Full anesthesia is estimated by insensitiveness of the cornea. It is also indicated by stertorous breathing, or by complete relaxation of the muscles. Directly the cornea becomes insensitive, or the breathing becomes stetorous, the inhalation should be stopped. The breathing may become stertorous, while the cornea is still insensitive. The rule to stop the inhalation should, notwithstanding, be rigidly enforced and it will be found that the cornea always becomes insensitive within a few seconds afterward. It is only necessary to add that the patient should be so dressed for an operation that his respiratory movements can be easily seen by the chloroformist. In the climate of India this is not difficult to manage, but it is rather more so in the climate of Europe ; so that in this respect, and this respect alone, the chloroformist in England and America is placed at a distinct disadvantage compared with the chloroformist in India.

NOTE.—Since writing this report two important papers upon this subject have appeared in the London *Lancet*. The one by Gaskell and Shore, in which they carried out a line of ingenious cross-circulation experiments, and from which they conclude that the fall in blood pressure seen under chloroform is due to cardiac rather than vasomotor depression ; and another paper published by Lawrie, in the London *Lancet* for February 11, 1893, in which he refutes the statements made by Gaskell and Shore, and details, experiments which he believes combat those of the two investigators just named.

The concluding paragraph of Lawrie's latest contribution to the subject states the facts so clearly and is so in accord with what we have tried to set forth in our own report that we can do better than quote the paragraph:

"The Hyderabad Commission's work proves that, while Syme's principles are right, there is no such thing as a safe method of chloroform administration. It is no longer a question of the superiority of the London method or of the Edinburg method ; absolute safety can be attained neither by watching the respiration nor the pulse for signs of danger—which are in either case proof of improper administration or of overdosing. Moreover, overdosing may take place whether the anesthetic is given on lint or on a towel or on a cap such as we use, or with Junker's or Skinner's or any other form of apparatus. The all-important point is that the breathing shall never be interfered with in any way. Safety under chloroform can unquestionably be insured, but it can only be so by attending to regular natural breathing; and, whatever method is employed, no one can deny that it is the bounden duty of the chloroformist to maintain natural breathing throughout the whole period of administration. To maintain natural breathing requires careful training and considerable experience, but if those conditions be fulfilled it is impossible to produce anything with chloroform but anesthesia; and the Hyderabad Commission has shown that anesthesia alone is entirely free from risk," provided the drug is not pushed too far and that the patient is in ordinary health. We would prefer to make the last sentence read: "Anesthesia can be safely produced by chloroform."—*Journal of the Amer. Med. Ass.*

DIAGNOSIS OF EPILEPSY BY THE URINE.—Dr. Gilles de la Tourrette claims that a diagnosis between hysterical epilepsy and that due to neoplasm can be made by the examination of the urine. He has found that there is an increase in the elimination of urea and phosphates during a convulsion due to a tumor, while the amounts excreted during an attack of hysterical epilepsy are diminished.

## HYPNOTISM AND SUGGESTION.

The interesting experiments carried out by Krafft-Ebing, at a recent meeting of the Vienna Society for Psychiatry and Hypnotism, have aroused great interest in scientific circles. The experiments were made with the object of showing that it is possible, by hypnotic suggestion, to transfer persons into a former period of their lives, their mental condition, at the same time, undergoing a corresponding change, and that while in this state nothing is lost to their memories which cannot, by suitable influence, be recalled. The astonishing results obtained with Miss P. by hypnotic suggestion are the more seriously considered, because brought to notice by so learned an observer as Krafft-Ebing. The subject was a woman of 33 years of age. Krafft-Ebing hypnotized her, and transferred her successively back to the ages of 7, 15, and 19, restoring her, after each experiment, to her normal condition. In each case she behaved, spoke, and wrote in a way corresponding to the age which she imagined herself to be. The experiments were received, by the majority of those present at the meeting, with much skepticism. In decided contrast with the opinions of certain psychologists and neurologists, who, while they doubt the genuineness of the three states shown in Miss P. by the demonstrator, still admit their possibility, stand the views of Professor Benedikt, who addressed Krafft-Ebing's hearers in a way quite characteristic of his energetic manner: "Well, the whole thing is a swindle. The possibility that such things may be presented before a scientific assembly, and that they are not at once recognized as a clumsy deception, is accounted for by the fact that the physicians and psychologists present do not possess a true knowledge of humanity, and are unable to make a correct analysis of such proceedings. One of the most interesting subjects of psychology is the fact that intellectual, physically and morally sound women are not those who are fascinating to men, but, on the contrary, the hysterical women; this results from the fact that the hysterical women presents the feminine type, even to the verge of caricature, and, according to the law of contrast, calls forth the admiration of the masculine sex. These hysterical women also have the feminine peculiarity of profiting by the intellectual, moral, or æsthetic weaknesses of the male sex. It is, therefore, a great satisfaction to them to get the better of any enthusiast, 'poseur,' or learned man. When we also consider that idle, lazy members of the higher classes of society require a special science for themselves, which they can pursue without labor or special knowledge, it becomes evident why medical doctrines and occurrences which tickle the fancy and self-sufficiency of these idlers so easily become the fashion. The teachings of Kneipp are naturally more accessible than those of Skoda, and these gentlemen can amuse themselves with all the fantastic nonsense of modern hypnotism and modern suggestion, and look down upon their more-learned fraternity, who do not accept such vague and uncertain theories. I belong to those who have long been occupied with the study of hypnotism, and have used it as a curative agent. If I did not immediately decry the exaggerations originating at Nancy, it was because frequently, in medicine, the truth has only left its impress to posterity clothed in a heavy garb of errors. The phantoms and the humbug pursued for years I have combated with success in Paris, in 1889; in Bournmouth, at the meeting of English physicians, in 1890; and in Brussels, the same year. The misapprehensions into which some noble minds, such as those of Charles Richter and Luys, have fallen stand to-day under the judgment-sword of the scientific world, which not only combats hypnotism, but warns and protects itself against its exaggerations and misuses."

It may be here stated that this form of suggestion is not particularly new. Seven years ago, similar experiments were made in Finland by Prof. Karl Hansen, of Copenhagen, who, later on, also made further experiments of the same kind. Hansen transferred the subject to a period of old age, and it was most interesting to note how the posture and even the facial expression corresponded with the period suggested. In the Paris and Berlin scientific circles the Vienna experiments call forth much ominous headshaking. The opinion seems to be pretty general that Krafft-Ebing has been made the victim of a very cleverly perpetrated deception,—by no means the first.—*Ed. Univ. Med. Jour.*

# CURRENT LITERATURE REVIEWED.

THE AMERICAN JOURNAL OF OBSTETRICS for October. Dr. Francis Foerster contributes a paper on

**Comparative Microscopical Studies of the Ovary,**

the paper in this issue being devoted to the study of the corpus luteum of pregnancy. He sums up the results of his comparative studies on the subject as follows:

1. The corpus luteum is a new formation of tissue, filling the loss of substance after the rupture of a Graafian follicle and fructification of the ovum.

2. In its production not only the wall of the ruptured follicle, but also the tissue of the ovary next to the follicle, and probably the remnants of the follicular epithelium, participate; thus the corpus luteum is considerably larger than the space occupied by the original follicle.

3. The corpus luteum is, in its earliest stages of development, of an embryonal or medullary or indifferent tissue, similar to that of the embryo in the first weeks of its growth.

4. The medullary tissue is the outcome of changes identical with those termed inflammatory. Fibrous connective tissue, smooth muscular fibres and blood vessels break up by proliferation of their living matter, both of the protoplasm and basis substance, into indifferent corpuscles, united among themselves, representing the embryonal tissue.

5. The human corpus luteum of the second month of pregnancy is composed of a lobulated, cortical portion of embryonal and a central portion of myxomatous tissue. The corpora lutea of the sow, the ewe, and the cow are non-lobular and uniform in structure throughout

6. The medullary elements, originally arranged in groups, produce by coalescence large, nucleated, protoplasmic bodies, the lutein or epitheloid cells of authors. They are pigmented by the hemoglobin of the extravisated blood corpuscles first filling the cavity of the ruptured follicle.

7. The large, coarsely granular, protoplasmic bodies should be termed "endothelia," and the tissue building up the corpus luteum "endothelioma"—*i. e.*, myxomatous tissue, in which the protoplasmic bodies persist instead of being infiltrated with basis substance.

8. The tissue of the corpus luteum is similar to that of a granuloma. The former is the result of a physiological, the latter a pathological reparative process. Both are myxomatous tissue.

9. In the corpus luteum the meshes of the myxomatous tissue remain throughout its persistence protoplasmic in the shape of coarsely granular, nucleated bodies, the endothelia. In the granuloma the meshes are soon infiltrated with myxomatous basis substance.

10. In the process of involution of the corpus luteum the endothelia break up into medullary corpuscles, which build up fibrous connective tissue. This process is often, but not invariably, accompanied by the appearance of clusters of hematoidin crystals.

11. The hematoidin crystals have a threefold source; red blood corpuscles contained in partly obliterated blood vessels; small extravasations of blood in the retrogressive changes of the venous and capillary blood vessels of the corpus luteum; and, lastly, the endothelia themselves, saturated with hemaglobin from their very origin.

12. The final result of the involution of the corpus luteum is cicatricial tissue, built up first by myxomatous, later myxo-fibrous, and at last by fibrous connective tissue.

The paper is illustrated by woodcuts of the microscopical appearance of the corpus luteum in the human subject and in animals.

Dr. J. Clifton Edgar presents a paper on

**The Mechanism of Labor; Some Experimental and Clinical Observations.**

As the result of his investigations he comes to the following conclusions:

1. The chief factor in determining anterior rotation of the lowest portion of the presenting part is the resistance of the pelvic floor.

2. Complete forward rotation of the presenting part is the rule in primiparæ; it often fails in multiparæ.

3. Excessive rotation of the head is a rare condition.

4. A permanent occipito-position is more common in multiparæ than in primiparæ, other things being equal.

5. Complete shoulder rotation occurs with about equal frequency in primiparæ and multiparæ.

6. In primiparæ and spontaneous delivery the anterior and posterior shoulders appear with about equal frequency.

7. In multiparæ and spontaneous delivery the posterior shoulder appears first more frequently than the anterior.

8. In spontaneous delivery the posterior shoulder is born first more frequently in both primiparæ and multiparæ—three times as frequent as the anterior in primiparæ, two and a half times as frequent in multiparæ.

9. The posture of the parturient does not appear to affect the mechanism of shoulder delivery.

10. Manual extraction of the shoulders was found to increase the percentage of perineal lacerations.

Dr. Giles S. Mitchell presents the report of

**The Second Successful Cæsarian Section Performed in Cincinnati.**

The operator did not flush out the abdominal cavity nor wash out the uterus. In closing the wound in the uterus, only one row of sutures were passed, which went through the peritoneal coat of the wound. The sutures were not passed till firm contraction of the uterus had taken place. The vagina was not irrigated, nor was any drainage tube put into the os, as at the time of the operation there was sufficient dilatation of the os to secure free drainage, since the patient had been

in labor for fourteen hours. On the twelfth day the patient had an attack of puerpural mania from which she happily recovered. The patient was allowed to convalesce without any meddling with the lochia or washing out of the wound. The lochia were normal and there was no odor from them.

Dr. Edward Sanders discusses "Chronic Oophoritis and its Treatment by Electricity." The author presents a number of statistics to show the futility of operation in this form of disease, contrasting these with the good results obtained by him from the use of electricity. He concludes "that for the cure of chronic oophoritis there is no remedy now before the profession which is the equal of electricity; the cure being obtained without any risk whatever to the patient, be the case simple or complicated, recent or of old standing, the only contra-indications being the presence of pus, the occurrence of acute peri-uterine inflammation, or the existence of old unyielding adhesions."

Dr. Joseph B. Bacon contributes a paper on the "Relation of Rectal Disease to Gynecology" in which he shows that the cause of pelvic inflammation often lies in ulceration of the rectum and urges that if the gynecologist would more thoroughly examine the rectum in those cases of pelvic abscess so intimately adherent to that organ that it is impossible to remove the sac without making a fistula, he would find, on looking up the history, that many of the cases originated from ulcers of the rectum.

Other papers in this issue are: "The Present position of Pelvic Surgery," by Dr. L. S. McMurtry; "The Relation between the Eyes and Diseases of the Female Genital Organs," by Dr. Boerne Breetman; "Five Cases of Laparotomy," by Dr. Lucy Waite; "A New Pelvimeter," by Dr. James B. Bullitt; and "The Removal of the Ovaries and Tubes in the Insane and Neurotic," by Dr. Archibald Church, a notice of which has appeared in THE MEDICAL AND SURGICAL REPORTER, for August 5th, 1893, page 227.

---

THE VIRGINIA MEDICAL MONTHLY

for October. Dr. John N. Upshur discusses

**The Therapeutic Application of Chloroform in Labor.**

He claims that chloroform diminishes the excitability of the muscular system and its capacity for work. If prolonged, it exhausts muscular irritability, it interferes with oxidation of the blood, and thus becomes toxic to the fetus. Its stimulant action on the vaso-motor center is doubtful. The indications for its use are in those cases where the pains are nagging and exhausting, in rigid os and in great nervousness and restlessness. The author believes that it should not be administered until the second stage of labor is well established (except in cases of rigid os), and at the latter part of that stage, and withdrawn as soon as the occiput has passed the ostium vagina. He considers that by the use of chloroform the uterus is left in such condition as to make subinvolution, with all the ills that follow in its train, almost inevitable. The spongy condition of the womb makes the patient much more liable to septic infection. By its use labor is often suspended, nor on the withdrawal of the chloroform will the pains return with desirable efficiency and instrumental delivery may be made necessary. The interference with the oxidization of the blood endangers the life of the child and he asserts that its use in natural labor increases the per centage of stillbirths. It is a question if death of the mother occuring within twenty-four hours after delivery, and reported as heart-clot, etc., may not have been due to the depression from too long continued administration of chloroform, plus the shock of labor. The author would lay down the proposition as an axiom, that whenever chloroform has been administered, a full dose of ergot should be given as soon as the head is delivered, or the second stage of labor complete. He would also suggest that it is a safe practice to give a full dose of quinine (gr. x) at the beginning of the second stage of labor when chloroform is exhibited, or belladonna, or one or more doses of nitroglycerin; especially will this last tend to antidote the nausea following chloroform administration. The hypodermic injection of atropine (gr. $\frac{1}{120}$) or sulphate of strychnia (gr. $\frac{1}{60}$) will undoubtedly add to the safety of the patient.

We must not lose sight of the fact that in the obstetric use of chloroform (which is usually conceded as the safest field for the use of chloroform), the patient is much longer under the influence of the anesthetic, and that the stimulus of constantly recurring uterine contractions, of a painful character, which are supposed to antidote the ill effects of the chloroform by constantly arousing the patient, may be absent or fail to exercise the stimulant effect usually a consequence of pain. The author urges that chloroform be placed on the same platform as other drugs and not be administered unless the indications of the case demand it.

Dr. Victor C. Vaughn contributes a paper on

**The Causes of Typhoid Fever.**

The author believes that there are many several germs that may cause ulceration in the intestines and an elevation of temperature in the lower animals. The germs obtained from the spleens of persons dead from typhoid fever, in this country at least, do not show uniformity in growth. For the last twelve or fifteen years the author has been called upon officially to investigate nearly every epidemic of typhoid fever which has appeared in the state of Michigan. In all cases the water supply has been examined, and during the last four years this examination has included a thorough bacteriological study. In no case has he been able to find in the water a germ wholly identical with that of Eberth. During the last year he has in each epidemic obtained the spleen of one or more persons whose death was caused by the fever, and in this organ he has found germs identical with those found in the water but not identical with the Eberth germ.

Dr. Reginald H. Sayre furnishes

**A Contribution to the Study of Club Hand.**

The paper is an abstract of that read by the author at the Pan-American Congress. Club-hand, he states, is very much less frequent than club foot. It may be acquired as a result of paralysis of certain muscles, or contraction of others from central nervous irritation, by cicatrices resulting from burns, or it may be due to injuries to the bones of the hand or fore-arm, or it may be congenital.

The congenital club-hands may be divided into three varieties:

1. Those where the skeleton is complete and well formed;

2nd. Where the skeleton, is complete, but ill formed.

3rd. Where the skeleton is incomplete and distorted.

Various writers say that the majority of cases come under the third head but the author's personal experience does not agree with this. In many cases club-hand is associated with club-foot or some other abnormality of development. The direction of the deformity may be either in flexion, extension, abduction or adduction or a combination of the two, the most frequent being the radio-palmar variety.

In those cases where the all the bones of the hand and fore-arm are present, the prospect of a good result are more favorable than where there is absence of one or more bones; and in these milder cases, when seen early. it is sometimes possible to restore the hand to proper shape and function by constant manipulation and rotation of the parts, which are to be held in their improved position by some fixed dressing, as the plaster-of-Paris bandage—the dressing being changed from time to time as the deformity is reduced.

Section of the tendons, ligaments or fascia may be necessary, if the case is not seen in the early stages. Many of these structures are so situated as to make open section preferable to the subcutaneous method; and if the flexor tendons have to be divided, it would seem better to operate in the fore-arm instead of the hand, and to split the tendon longitudinally, and after having gained such additional length as was needed by sliding the ends past each other, to suture them together once more.

Dr. Charles G. Cannaday contributes an article on "Subinvolution of the Uterus, and Its Treatment by Eiectricity" urging its use in this disease and stating that the trouble can be cured in one half the time required by other methods of treatment.

Dr. Luther B. Grandy furnishes an interesting article entitled "A Contribution to the History of the Discovery of Modern Surgical Anæsthesia," presenting some new data relative to the work of Dr. Crawford W. Long, whom the author regards as the real discoverer of the anæsthetic properties of ether.

Under "Clinical Reports," Dr. R. K. Smith contributes an interesting report of

**An Atypical case of Cerebral Meningitis.**

In this case the respiration failed thirty six hours before the heart ceased to beat; artificial respiration being kept up during this period.

The special features of interest in this case are: First. The mild symptoms—*i. e.*, the noticeable absence of pain until the day that he became unconscious; photophobia, delirium, muscular contractions, etc. etc.

Second. The sudden loss of consciousness and the high elevation of temperature at the same time; and then the rapid fall of the temperature.

Third. The cessation of the respiratory act while the cardiac function remained unimpaired for quite a while.

Fourth. The length of time his heart continued to beat after the normal respiratory act had ceased, which was thirty-eight hours and thirty minutes, during which time artificial respiration was performed. If the respiratory act was withheld, the surface would gradually get darker in color; the heart faster and weaker.

Fifth. The suspension of action of all the reflex centres, both cerebral and spinal, with the exception of the vaso-motor, cardio-inhibitory (?), vesical, and rectal.

The remaining papers in this tissue are: "Personal Experience in observing the Results of Good and Bad Sanitation in the Confederate States Army," by Dr. Bedford Brown; and "The Use of the Catheter During Labor," by Dr. R. A. Lancaster, in which the author urges the use of the catheter as a routine practice at beginning of the second stage of labor.

---

**Extirpation of the Wounded Spleen.**

Riegner (*Berliner Klinische Wochenschrift,*) reports the following interesting case: A boy, fourteen years old, fell from a high scaffolding, striking upon the abdomen. When seen the patient was extremely pale, and was vomiting a brownish fluid. The abdomen was markedly distended and very tender, and there was retention of urine. Rupture of one of the large abdominal viscera being suspected, laparotomy was performed, notwithstanding the shocked condition of the patient. The spleen, which was found completely torn through, was removed after ligation of the vessels. Two sub-cutaneous injections of 300 grammes of a 0.6 per cent. solution of sodium chloride were administered. Twelve days after the operation the sutures were removed. Several weeks later it was found necessary to amputate the left thigh for gangrene, but despite these two severe operations the patient recovered. At the present time there is a general enlargement of the external lymphatic glands, and also enlargement of the mesenteric glands. It would, therefore, appear as if the lymphatics had assumed the function of the spleen. The relation of the white to red corpuscles was at first 1:100; the absolute number of the red corpuscles rapidly increased up to normal; that of the white corpuscles did not decrease.—*Univ. Med. Mag.*

# PERISCOPE.

IN CHARGE OF WILLIAM H. BRICKER, M. D., B. SC.

## MEDICINE

### Enchondroma of the Mammary Gland in a Bitch.

At a recent meeting of the Montreal Medico-Chirurgical Society, Dr. Adams brought before the Society a case of this condition on account of its rarity. Enchondroma has been very occasionally reported as occurring in the female, perhaps more frequently in the domestic animals. The present specimen, a bullet-like growth two and one-half inches in diameter, was obtained from a setter bitch. The growth would seem to be of less than a year's duration, and to have originated after a rather severe mammits. The bitch had a litter of puppies in February, 1892. There was some difficulty about the weaning and one of the teats became injured and inflamed. The bitch recovered, but in the autumn a small lump was observed in the previously injured teat. It was removed at the beginning of last month.

The structure of this tumor is typical, it is slightly lobulated, and the center is of bony hardness. Sections showed the lobules towards the periphery to be of hyaline cartilage, with some regions presenting stellate cells and less dense matrix; they were separated by bands of fibrous tissue. Deeper down the matrix became impregnated with calcareous salts, but even at the center there was not true bone. There were large channels in which ran the blood vessels surrounded by loose cellular structure, but the surrounding osteoid framework possessed neither proper Haversian canals or true lamellæ. Langlois, in the *Dictionnaire des Sciences Medicales*, gives a good account of these mammary enchondromata.—*Montreal Medical Journal.*

### The Hereditary Transmission of Immunity Against Rabies, from the Father to the Offspring.

Tizzoni, Guido and Cetanni, Eugenia (*Centralbl. f. Bakt. u. Parasik.*) These investigations were made with the express purpose of determining the transmission of immunity by the semen of the father to the offspring The results were as follows:

(1) The father can transmit acquired immunity against rabies to the offspring through the semen.

(2) This occurs without any peculiar influence on the part of the mother, as the father can transmit the immunity to the offspring of different mothers.

(3) The immunity thus transmitted extends equally to all the progeny.

(4) The immunity of the young is less than that which the father possesses.

(5) The immunity transmitted through the seamen is permanent, in distinction to that acquired through milk or injected blood, which is transitory.—*Univ. Med. Mag.*

### The Preventive Treatment of Tetanus.

Simmons says it is best to kill the tetanus bacillus while they are yet confined to the point of introduction. The following procedure is recommended in all cases of punctured wounds: All foreign substances are removed, and the wound thoroughly cleansed. With a gold hypodermic needle and an ordinary syringe he injects into the wound, if painful or sensitive, a 4 per cent. solution of cocaine, which is allowed to remain until its full effects are produced. He then draws out what may remain within the wound, and with the same instrument injects the following:

℞
Nitrate of silver..... grs. v.
Water. ..... f ʒ ss.

Or

℞
Corrosive sublimate ..... grs. ij.
Carbolic acid..... grs. xv.
Alcohol ..... f ʒ ss.

*Internat. Jour. of Surg.*

### The Advantages of a Physician Dispensing His own Medicine.

1. To make a physician more independent.
2. On account of the habit of substitution prevalent among certain druggists.
3. To make sure of exhibiting pure and fresh drugs.
4. To prevent refilling of prescriptions without the physician's knowledge.
5. To show his disapproval of the practice of counter prescribing and the selling of patent medicines.
6. To center the pecuniary profits upon the physician.
7. To assure cleanliness in the preparation of medicines.
8. To educate the doctors to practical pharmacy.
9. To inspire confidence in the patient.
10. To check the growing use of proprietary medicine by the profession. Dr. Storrs. —*Medical Age.*

### Calomel Soap in the Treatment of Syphilis.

Watraszewski (*Ann. de Derma. et de Syphil.*, 1893) describes the preparation of the soap as follows: The calomel, in the form of vapor, is mixed with a potash soap, in strength of one to two and one to three. It forms a soft mass of a white color.

From two to three grammes of the soap should be rubbed in every day.

The inunctions should be carried out in the following manner: The parts to be rubbed should first be washed with ordinary soap and water, and the patient then having taken a bath, the soap should be applied and rubbed in with a rotary motion of the hand for from ten to fifteen minutes.

The advantages claimed for this method of treatment are as follows:

1. Its application takes but little time.
2. The soap is odorless and colorless, and it does not soil the linen.
3. The inunctions never irritate the skin, except when applied too often in the same region.

The rapidity of cure corresponds in time to that resulting from the use of blue ointment.

---

### Treatment of Infantile Convulsions.

M. Jules Simon advises the following method:

1. Relieve the digestive organs by a laxative, or by tickling the throat until vomiting occurs.
2. If the attack continues, give ether or chloroform by inhalation.
3. Administer within twenty-four hours the following anti-spasmodic mixture:

℞

| | |
|---|---|
| Chloral Hydrate | aa gm. 1 |
| Bromide of Potash | |
| Syrup of Codeine | gtts 10 |
| Tincture of Musk | |
| Tincture of Aconite Root | gtts 10 |
| Orange flower water | gm 100 |

4. If the attack is grave and prolonged, place the patient in a warm bath, and apply, with suitable antiseptic precautions, a small blister to the back of the neck, or to the epigastrium, leaving it in place not longer than three hours. As soon as vesication is established, substitute a poultice for the blister.—*Union Medicale.*

---

### The Mechanical Treatment of Locomotor Ataxia.

Hirschberg (*Bull. Gen. de Therapeutique,*) coucludes as follows with regard to the utility of Frænkel's plan of treatment of locomotor ataxia:

1. It is possible to greatly improve the ataxic movement in tabetics by the method of Dr. Frænkel.
2. The gymnastic exercises explain the reason of augmentation and development of muscular force in the affected members.
3. The exercises in making the muscular contractions under the control of the will of the patient ameliorate the inco-ordination.
4. In bettering the *morale* of the patient by giving him more confidence in his extremities, the persistent ideas of pathophobia which cause so much misery in tabetics are dispersed.
5. The treatment is indicated in all stages of locomotor ataxia. Best results, however, are obtained when it is instituted before locomotion becomes completely impeded.
6. Treatment is contra-indicated when the course of the disease is very rapid; that is to say, when the clinical picture is completely developed in less than two years; also, when the general condition of the patient is particularly bad, and especially when the articulations are affected.
7. The treatment does not exercise any influence on the cardinal symptoms of tabes dorsalis, with the exception of the ataxia.

It might be said that Frænkel's treatment in principle distinguishes three categories of movements:

1. Simple muscular contractions; that is to say, of one muscle or a physiological series of muscles.
2. Simple co-ordinate movements; for instance, touching the end of the nose with the index finger.
3. Complex co-ordinative movements, such as writing.

In applying the treatment, the practice is to begin with the simpler passive movements, then gradually assume the more complex.—*Jour. Nerv. and Mental Dis.*

---

### Ord (W. M. and White (E.) on Certain Changes Observed in the Urine in Myxœdema after the Admistration of Clycerine Extract of Thyroid Gland.

From a careful study of a case, the following deductions are made:

1. That the urine is increased in volume.
2. That the nitrogen excreted in the urine exceeds the total quantity of nitrogen in the food.
3. The phosphoric acid and chlorine eliminated are practically unaffected.
4. That the increased nitrogenous excretion is chiefly in the form of urea.
5. That the body weight is rapidly diminished.
6. That the temperature of the body is raised.—*Brit. Med. Jour.*

---

### Uffelmann (J.). Can Living Cholera Bacilli be Carried with Dust through the Air?

Thin layers of finely powdered garden-earth, fine white sand, street- and floor-sweepings, and mixtures of dust and diarrhœal discharges, were moistened with cultures of cholera bacilli. They dried in fourteen to sixteen hours, and were then pulverized. At various intervals of time cultures from these mixtures were obtained by inoculation and by allowing the dust disturbed by being blown upon to settle on gelatine planes. The results of all the experiments were the same. While the bacilli died rapidly during the process of drying, some of them were still alive after the lapse of twenty to twenty-four hours, if sun-light were excluded, were carried about with the dust, and developed colonies. As an exception solitary bacilli survived three days. The lesson is clear. Although the slight liability of the materials soiled by choleraic discharges to the formation of dust, and the rapid death of the bacilli in drying substances (materially hastened by the action of sunlight), render the propagation of cholera in this mode exceptional, it is, nevertheless, possible for living cholera bacilli to be carried with dust through the air, and to infect food, water of streams, etc., or to enter our mouths.—*Berliner klin Wochens.*, June 24, 1893.

## SURGERY.

### Ingrowing Toe-nail.

Dust over the granulations at the bottom of the sulcus with aristol or iodoform and on top of this put a small piece of lint or cotton.

Take a piece of rubber bandage one-half inch wide and twelve to fourteen inches long and, if it is the inside of the toe that is affected carry the bandage over the nail toward the inflamed structure. This, as you will observe, will have a tendency to carry the mass away from the nail. Beginning at the extreme end of the toe, carry the bandage back, with such pressure as the patient can comfortably stand, until the whole area of inflammation is included. Fasten it by means of a light gum band or tapes fastened to the end of the bandage.

The patient is then able to attend to his ordinary duties. The bandage can be removed at night and re-applied by the patient himself, if desirable, the first thing in the morning.—*N. Y. Med. Times.*

## GYNECOLOGY.

### Ludlam on the Physiological and Morbid Relations Existing Between the Uterus and the Eye.

Janot's work is based on the following conclusions :

1. Certain ocular troubles exist in relation with different physiological and pathological conditions of the uterus.

2. In order to institute an efficacious treatment it is important to establish their origin.

3. These ocular lesions are much more tenacious when the uterine troubles have persisted for a long time.

4. In a large share of cases they are attributable to infection.

5. The treatment should be addressed to the local condition of the uterus and the vagina, to the local state of the eye, and to the general condition of the patient.—*N. W. Med. Times.*

### Report of six Consecutive Cases of Extra-Uterine Pregnancy. With a Clinical Report of four Additional Cases, Dr. Hall offers the Following Conclusions.

1. All cases of intra-peritoneal rupture of a tubal pregnancy are not followed by marked collapse, and this fact should not be overlooked and thus a mistaken diagnosis made.

2. If the rupture takes place in the early months of gestation and does not immediately prove fatal, the patient may, and frequently does, improve, and all of the symptoms disappear for a week or more, until another hemorrhage takes place; and this may occur several times.

3. All cases of tubal pregnancy should be operated upon at once after the diagnosis is made.

4. The operation is not a dangerous one, and, if made early, before the patient is exsanguinated, the prognosis is as favorable as many other abdominal operations, and much more favorable than by any other method of treatment,—*Cinn. Lancet Clinic.*

### Menstruation in a Child Aged Six.

Jacobvitch (*Nouv. Arch. d'Obstet. et de Gynec.*) related this case before the St. Petersburg Society for Diseases of Children. At the age of three she was brought to Jacobvitch for hemorrhages. The genitals were normal. A considerable amount of a milky fluid exuded from the breasts, which were of the size of hen's eggs. The child is now over six years of age. She menstruates several times yearly, especially in summer. The period lasts from three to four days. Before the catamenia the child becomes ill-tempered; afterward she has headaches with vertigo. She is very anemic. The breasts are as large as small oranges; the labia minora and clitoris slightly hypertrophied.—Boston *Med. and Sur. Jour.*

## OBSTETRICS.

### The Influence of Treatment of a Syphilitic Mother, Especially During Pregnancy, on the Health of the Infant.

Etienne draws the following conclusions from the study of thirty-two cases of pregnancy in syphilitic women :

"1. The fetal mortality, in cases in which the mother has been treated, is enormous, reaching 85.5 per cent. If treatment be applied throughout pregnancy, we may hope to obtain almost complete immunity from this infant mortality.

2. Syphilis attacks the fetus especially during the fifth, sixth, and seventh months of intrauterine pregnancy.

3. Paternal syphilis is less injurious to the fetus than maternal syphilis.

4. The prognonsis differs according to the stage of pregnancy when the mother becomes contaminated.

(*a*) If infection occurs during the first three months, and is not treated, the mortality during the first few days after delivery reaches one hundred per cent.

(*b*) The prognosis is a trifle better, if infection occurs during the fourth and fifth months.

(*c*) In one case of infection at the eighth month, the child lived and was apparently healthy; in a second similar case the child was in good condition at birth, but developed symptoms of syphilis later.

(*d*) Whenever suitable treatment was administered, the mortality was *nil.*

(5) In no case were any unfavorable results met with from internal medication during pregnancy."—*Amer. Jour. Obst.*

## Galenical Preparations

MANUFACTURED BY

## WILLIAM R. WARNER & CO.

MANUFACTURERS OF SOLUBLE COATED PILLS.

FOUNDED 1856

### Standard and Officinal Preparations for Physicians Only.

#### PIL. PHOSPHORUS, DAMIANA ET NUC VOM.

(Warner & Co.)

℞ Ext. Damianæ, 2 grs. | Phosphorus, 1-100 gr.
Ext Nuc. Vom. ⅜ gr.

Med. prop.—Aphrodisiac. Dose, 1 to 2 pills.

Of this combination it has been said: "It re-illumes the fading spark and revives the vital forces."

PER 100, 90 CTS.

#### PIL. ALOIN, BELLADONNA AND STRYCHNINE.

(Warner & Co.)

℞ Aloin.....1-5 gr. | Medical properties—
Strychnine.....1-60 gr. | Tonic, Laxative.
Ext. Belladonna..⅛ gr. | Dose, 1 to 2 pills

Try this Pill in Habitual Constipation.

PER 100, 90 CTS.

#### Pil. Sumbul Comp.

(Warner & Co.)

DR. GOODELL.

℞ Ext. Sumbul . . 1 gr. | Ferri Sulph. Ext. . . 1 gr.
Asafœtida . . . 2 gr. | Ac. Arsenious . . 1-40 gr.

"I use this pill for nervous and hysterical women who need building up" This pill is used with advantage in neurasthenic conditions in conjunction with Warner & Co.'s Bromo-Sodc, one or two pills taken three times a day.

PER 100, $1.00.

#### Pil. Lady Webster.

(Warner & Co.)

℞ Pulv. Aloes . . 2 gr. | Pulv. Rose leaves . ½ gr.
" Mastich . ½ gr. | M. Ft. one pill.

This is an excellent combination officinally designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when taken in doses of one pill after dinner.

PER 100, 25 CTS.

☞ BY ALL DRUGGISTS OR BY MAIL. ☜

## VOLUNTARY TESTIMONIALS

From such eminent Physicians as Paul F. Munde, J. Lewis Smith, Thos. E. Satterthwaite, Graeme M. Hammond, Geo. B. Fowler, Stephen Smith Burt, Dr. A. Jocobi, Mary Putnam Jacobi, B. Sachs and scores of others, who are using

## RUDISCH'S BEEF PEPTONE

(SARCO PEPTONES)

in their Private and Hospital practice, should certainly convince the most sceptical practitioner of its unequalled value as a Food for invalids, and patients with faulty or impaired digestion. Its palatability, its rapid assimilability and the fact that it contains all the nutritive elements of the best lean beef insure its superiority over all other forms of Beef.

Physicians are requested to write us for free **samples**, pamphlets, testimonials, etc. Mention this journal.

### PROBLEMS OF PUBLIC INTEREST CONCERNING THE INSANE.*

ORPHEUS EVERTS, M. D., College Hill, Ohio.

There are several problems of public interest involved in the present relations of society to the insane. Among the more important of these are questions of dependency, of curability of the insane, and of the preventibility of insanity.

Each of these questions presents two aspects for consideration—one appealing to whatever altruistic sentiment may have been developed with our growth, and the other to that selfish sentiment that is common to the race.

That there is a large number of insane persons, increasing rather than diminishing, in every civilized state, is a fact familiar to all intelligent interested observers.

That the insane constitute a dependent class of society is equally apparent.

Independence implies mental capabilities corresponding to impending necessities under any given circumstances. But few living beings are superfluously endowed for the end indicated. A large proportion of animal, as well as vegetable, specializations entering life upon terms of apparent equality, die prematurely because of inherent lack of capability to meet or resist the exigencies of environments.

The complex environments of civilized life require much greater capability on the part of individuals to maintain independence than are required by the more simple conditions of savagery.

Insanity implies mental impairment, hence lessened capability, noticeable as contrasting previous conditions manifested by the persons supposed to be insane.

Liability to become insane under ordinary provocation, is associated, as a general rule, with inherent defects of organization characteristic of a class of persons whose natural capabilities are below a common level at, or even above, which independence implies constant, anxious and often unsuccessful effort. A slight degree of impairment, therefore, may be sufficient to reduce a self-supporting person to a condition of dependency.

That exceptional persons of more than ordinary capability have become insane under exceptional circumstances—or that rare instances of exaggerated capability associated with some degree of mental disorder, have been observed—when properly considered should not discredit the foregoing statement or inferences.

It is true—if mental phenomena are sequential to cerebral activities orderly and disorderly, and reflect cerebral conditions sound and unsound—that it must be possible for whoever or whatever is endowed with brains to become insane under sufficient provocation. Fortunately for most of us, however, ordinary provocation is not sufficient to seriously derange the mental mechanisms of a large majority of mankind.

Neither should the fact that a considerable number of active and apparently capable, business men suffer and are destroyed by what is now familiarly known

*Read before the Mississippi Valley Medical Association, October 4, 1893.

as 'paresis,' affect the position taken unfavorably. Clinically considered, in the sidelights of commemorative circumstances, these men are found to be not exceptional persons—but belonging to a class not only liable to become insane because of inherited peculiarities, but constitutionally prone to indulgence in practices more than ordinarily provocative of cerebral disease.

Degenerative impairment—hence incapability of self-support—on the part of the insane being admitted, the questiou of public interest is: What shall be done with and for them? All savage peoples aid and abet Nature in her methods of disposing of the defective and incompetent, in all of her kingdoms, by neglects and practices quite as cruel as her own. Our own ancestors were not exceptional in this respect.

Among civilized peoples it has come to be recognized as expedient and dutiful for the strong of our kind to succor and sustain the weak, no matter what the burden may be. Why this is or how it came to pass, need not be discussed in this connection. Enough to say that it is an 'inevitable sequence of antecedent conditions;' that the duty is clear and will never more be shirked while our people advance along the lines of christian civilization. It is our privilege, however, to consider 'ways and means' for the accomplishment of this end in a severely practical light. The problem then is: how shall this recognized obligation be discharged with the least expense to ourselves?

This depends, of course, upon the kind of provision for the dependent insane demanded by our sense of duty enlightened by sympathy as well as intelligence. What shall it be? Not such as was extended to the insane of all christian lands from the accession of Roman ecclesiasticism in Europe to the close of the eighteenth century! O no! Not even such as was considered satisfactory in the earlier decades of the present century! Not by a long way! Public sentiment now demands for the dependent insane not only custody and treatment, but provision for all the privileges and comforts of life that they are capable of enjoying. And this is right. Nothing could be more just or humane; nothing easier of accomplishment: provided the accomplishment be referred to agents sufficiently instructed and informed of the various degrees and peculiarities of capability for enjoyment of the different classes of the insane, instead of to the conceited zeal of public ignorance, however well intended. Public ignorance and mis-information respecting insanity and the insane, have given rise to nearly, if not quite, all of the fadulent notions that have made themselves known by endless clamor respecting public provision for the insane of late years—wearisome enough to well-informed listeners, if not altogether unprofitable.

It has not been the purpose of the writer in preparing this paper to renew or continue the discussion of definite 'propositions' for the proper care of the insane, including location, buildings, organization and management, etc., of public hospitals or asylums, further than to submit a brief resumé of conclusions reached, or opinions entertained, after the experiences of twenty-five years service as superintendent of large and small, public and private hospitals for the insane, and interested studies of the characteristics, capabilities, and needs of various classes of dependent persons.

These conlusions have been summarized as follows:

(1), Intelligent provision for the insane implies provision for various classes, according to capabilities of enjoyment, and the exercise, under intelligent supervision, of variously impaired faculties.

(2), Public provision for whatever class of insane persons implies: housing, clothing, feeding, sanitary and moral discipline, amusement and employment for such as are capable of being amused or employed, and medical treatment for the sick: the essential features of such provision being, so far as may be practicable under given circumstances, adaptability to the needs of each distinctive class.

(3), Great, expensive, architecturally-imposing palaces, providing alike for all classes, however serviceable they may have been, æsthetically considered, in times past—as they unquestionably were—are no longer necessary nor appropriate for the ends indicated. Yet, so the insane are comfortably housed, each class according to its condition, it is comparatively unimportant whether they be so in large or small houses; cottages or palaces;

connected or detached; high or low buildings.

(4), It is important that the insane of all classes be well fed under careful supervision; but whether in large or small dining rooms, by groups, or aggregations, is of so little consequence that it should be a matter of convenience rather than of principle.

(5), It is important that public institutions for the insane be well-organized and administered; but whether by three or thirty trustees is a matter of but little moment. Partisan, or bi-partisan boards of directors, may be equally good or equally bad. The fewer statutory details for the government of such institutions the better. Good men will govern a hospital well under adverse statutes, and bad men will manage to evade the wisest legislation. The usefulness and reputation of a hospital for the insane will reflect the characteristics of those who direct or administer its affairs, rather than the laws by which they are authorized to act, or the political party to which they belong.

(6), It is wise to retain in office capable men, who have demonstrated their fitness by successful management of affairs, so long as their capability continue to be elastic; but the displacement of officials whose ideas have become insoluble by competent and still growing men, with or without special training, should not be regarded with alarm nor as of doubtful propriety. Capability without experience is more valuable than experience without capability in any executive position. Whatever ills attend 'rotation in office' in this country, a custom essential to the vigor if not the existence of partisan organization, without which republican government would degenerate—are among the evils compensated by the good of almost unlimited freedom. The trend of human progress is not seriously deflected thereby.

### ARE THE INSANE CURABLE?

That insane persons, in some instances, recover normal capabilities after impairment and disorder, is not a question but a fact. Whether or not such persons are greatly, or to any extent, aided to recover by what is done for them by public provisions for their treatment, is a question. How shall it be answered? There is no existing source of accurate information on the subject. Whatever answer is made must, therefore, be inferential and a matter of opinion only. There is a prevalent notion, whether well or ill founded, that the chance of recovery for an insane person is much enhanced by commitment to a hospital for treatment. A notion that emanated, probably, from general practitioners of medicine, who, as a class, are only too willing to escape the responsibility and annoyance of treating insane persons under ordinary circumstances; and has been confirmed by the claims of distinguished specialists administering the affairs of stately institutions, by which their occupation and pretensions have been greatly dignified.

As an economical problem it would be well to know more about this matter than is now known. If any considerable number of insane person are curable or will recover under hospital treatment, that would not recover otherwise, then it is a matter of economy on the part of the state to provide for such treatment, at an expense to be measured only by results. If the average life of a dependently impaired insane person is twelve years, and the average duration of disease of such as recover is one year, then the state can afford an extraordinary expenditure for the cure of the curable, as each recovery represents a saving of eleven years of maintance of an unrecovered person. It is not necessary to make more definite calculations; what we need to know is that the insane are amenable to treatment. That a large proportional number of insane persons are not curable, or recoverable under any known circumstances, can not now be denied in the face of facts the significance of which admits of but little question or modification. Men of experience and capability in the specialty to-day smile interrogatively or with incredulity at the pretensions of cure made by their not very remote predecessors in charge of hospitals for the insane. Statistics of hospitals, inconclusive as they necessarily are on most subjects requiring accurate and comprehensive information, are particularly so in relation to the question under consideration. Hospital authorities in bad repute because of their defects of construction and administration, sometimes exhibit a larger percentage of 'cures' than do the most reputable.

My belief, based upon observed facts

and rational inferences, is that no insane person who is not spontaneously recoverable under ordinarily favorable circumstances is curable by extrinsic influences of any kind. No insane person whose mental impairment is sequential to structural changes of tissues immediately implicated in the performance of mental functions, if of a pathalogical character, is spontaneously recoverable under any circumstances. By recovery I mean perfect restoration of normal conditions; not a partial restoration that may pass for 'cure,' that is after all, but repair.

Cicatricial tissues are always less complex, hence less capable, than the tissues which they replace in the process of reparation. Tissues by which lesions of continuity of skin or muscular fibres are repaired, are familiar examples of this law. It is not probable that brain-tissue is exceptional or exempt from so uniform a physiological process.

Recoverability from insane conditions is, therefore, limited to persons whose mental impairment is attributable to lesions of other than cerebral structures, whereby the brain may be temporarily deprived of its ordinary pabulum or supplied with vitiated nutriment, without impairment of its structural integrity; and 'curability,' is limited to such persons of this class as require the aid of more favorable circumstances than their ordinary environments supply or their means may command, to enable them to resist or overcome these conditions.

The problem of public interest in this connection then is:—has public provision for the insane furnished—can it be made to supply—essentially more favorable conditions for the recovery of the recoverable, than, as a rule, they otherwise enjoy?

That this question should be answered affirmatively I have no doubt.

Concentrated efforts therefore, should be made, backed by liberal expenditures and intelligently directed toward the creation of environments in every way conductive to the recovery of the recoverable: while provision for all other classes should be made with reference to their individual welfare and the utilization of such remnants of capability as they may be still possessed of, at the least reasonable expense.

It may be inferred from the foregoing that the writer does not estimate medicine as the most important factor in the problem of curative conditions for the insane. If by medicine is meant the administration of drugs or chemicals, the inference is a fair one. The insane can be medicated elsewhere as well as they can be in hospitals or asylums.

Hospital physicians have no mysterious knowledge of medicine—no specifics—no secret remedies.

Hospitals for the insane under the exclusive control of Doctors of Homeopathy, claim larger percentages of cure than do similar institutions administered by Doctors of Medicine.

The administration of medicine or the appearance of medicine, may still be wise, being responsive to the necessities of the multitudes who have not yet fully emerged from the shadows of primitive superstitions, nor so far departed from ancestral types as to be uninfluenced by the fetisch feeling that is common to the race, forever suggesting supernatural beings, designs, powers, activities and virtues in association with natural objects in explication of natural phenomena. There are material medicines, also, that are neither poisonous nor inert, that in the hands of skillful physicians contribute, unquestionably, to conditions essential to recovery, as above indicated. Medicines that can not be well omitted in the treatment of the insane under the most favorable circumstances. But these are not, or need not be, many—nor should too much dependence be placed upon their efficacy to the neglect of other and more important measures.

There are other uses, also, to which medicines are now being liberally appropriated in the treatment of the insane, that if not curative of those to whom the medicines are administered, are comforting to others with whom they may be necessarily associated—securing for the time-being silence and languor instead of raving and violence; and at the same time enabling the management to assure an admiring public of the fact that all restraints have been abolished from the hospital under their control, and the greatest reformation of the age has been accomplished by their benevolence and sagacity!

There may be wisdom in such an appropriation of means; knocking the insane down with chemical clubs and paralysing them with poisons instead of limiting

their movements by camisoles or protection beds;—but if so, it is wisdom of a kind unknown to my philosophy. There may be virtue in the practice—but if so, it must be of that kind that is said to be its own reward!

If the conditions favorable to the recovery of the recoverable insane do not consist of special medication or mysterious methods of treatment peculiar to hospitals for the insane—of what then do they consist?

They consist, in the first place, of the authority vested in or assumed by such institutions to control the conduct and prescribe the modes of living of the insane committed to them for custody and treatment. Secondly—notwithstanding the fad of the foolish that hospitals for the insane should be made as 'home-like' as possible—they consist of better sanitary surroundings, appurtenances and observances—in but few respects 'home-like' to the greater number of dependent insane persons to be benefitted thereby.

Third—not greater skill in medicine, but more knowledge of the insane on the part of doctors and nurses than is common to the profession—hence more rational treatment.

This is all! But indeed, this is much when considered in contrast with the ordinary home surroundings, modes of living and methods of dealing with the insane, characteristic of the population from which the insane are, for the most part, derivable.

These conditions well provided for, all the rest—minor matters about which so much babble has been heard, of mere 'annise and cummin' importance in hospital affairs—however interesting to persons incapable of appreciating weightier matters may safely be permitted to take care of themselves.

IS INSANITY PREVENTABLE?

Theoretically—yes! Practically—no! Theoretically, insanity is preventable—because so many of the so-called 'exciting causes' of insanity, in an ideal state of society would either not obtain or would be prevented. Practically, insanity is not preventable—because, human nature being as it is, an ideal state of society cannot be effected by any means at our command; nor otherwise than by the slow, however continuous, process of growth.

There are persons it is true, many and worthy in their way, who think otherwise and devote their energies persistently to the accomplishment of such ends. Persons who seem to be exceedingly sensitive to special objects but oblivious to the great fact of a Universe. Persons who interest themselves deeply in special subjects but fail to recognize the more important relations of parts to aggregates, or of generals to particulars, without which knowledge is of but little value. Persons who think, if at all, of the Universe as of a limited domain, governed by personal decrees of limited applicability and special providences to meet contingent emergencies as they arise. Persons who think of mankind as degenerate beings fallen from a high estate, moving upon a down-grade toward inevitable disaster—helpless of themselves, but for an arrest of whose downward progress they seem to think it only necessary to secure the enactment of some kind of a law, prohibitory or other, whereby the race may be restored to primitive conditions of innocence and happiness. These persons have their uses and play their parts in the great drama of human progress—failing of accomplishment, however, because the movements of mankind along the lines of civilization are not determined nor determinable by human prudence, wisdom or design, nor to be arrested or greatly modified by whatever protest, persuasion or statutory enactment, not in harmony therewith.

To prevent insanity, the fact is conspicuous that the antecedent conditions essential to its development must be so modified as to change the sequence.

What are the antecedent conditions essential to the manifestation of insanity?

(a), An inherent, consequently inheritable, peculiarity of organization, not common to the race but characteristic of a defective class of persons, and recognized, properly, as a structural 'potentiality of insanity.'

(b), Certain lesions of nutrition—whether from deprivation or excess—inanition, indigestion, intoxication, or inherited dyscrasias of various kinds.

(c), Exhaustion of organic energy transmutable by cerebral activities into mental force, by unusual or excessive expenditure in work or dissipation.

(d), Physiological limitations deter-

mined by germinal or spermatic conditions, by which structural types, growths, activities and longevities of individuals are dominated through every stage of existence, however influenced by external relations.

Of these antecedent conditions, some of which are essential to the development of insanity, it will be seen at a glance that not one of them can be successfully eliminated from present conditions of society, although there may be an ideal remedy for each.

The first mentioned, for example—that of inherited defect of organization—might be eliminated in time by countermarching the column of civilization and returning to primitive, or savage conditions of society, in which the defective drop out of the procession early in life because of their original incompetency to continue the effort required for existence, if not aided and abetted thereto by naturally instructed or instigated kindred, leaving only the more perfect to survive. But this we will not do; for whatever may be said or sung of the wisdom of nature and the beauty of things natural, no people having once reached a high plane of civilization by spontaneous effort has been known to return to barbarism or savagery. Disappointed and dissatisfied individuals occasionally seek the wilderness hoping to escape the exactions of good society morally and otherwise, but they represent exceptional characteristics.

Asexualization of the recognisably defective and constitionally vicious, criminal and otherwise offensive and unfit members of society by surgical interference, now safely practicable, would do this business in time. But however patent the fact may be that we are breeding criminals and lunatics and paupers and prostitutes at a constantly increasing ratio, as an inevitable sequence of our acts of benevolence and humanity—and that a compulsory solution of the problem will some day be made—it will require more than one 'campaign of education' to secure the adoption of so effectual, rational and beneficent a measure. Meantime it is a waste of energy to talk about prohibiting the legalization of marriages between defective parties as a remedy, as all obstructive marriage-laws contribute only to an increase of bastardy, feticide and kindred vices. The uniform demands of organic appetencies will not be satisfied nor held in abeyance, effectually, or to any considerable degree, by statutory enactments. Comets have never been deflected from their courses by papal bulls ; nor can the imperious sentiment of sex in man be suppressed by ordinances.

Many worthy persons now believe that the second conditions mentioned—so far at least as they may be incidental to alcoholic intoxication—can be corrected by law. But, however commendable their motives, or valuable their work consistent with such belief, the advocates of 'prohibitory laws' for the elimination of alcoholic intemperance from society must admit that the end is still far from accomplishment with but little probability of success in the near future.

There are other poisons, also, that are more efficient than alcohol as ordinarily used, in the provocation of insanity—poisons that are developed within the body—the presence of which is neither voluntary, nor recognized as vicious in a moral sense by unskilled observers,—but none the less indicative of depravity of organization, manifested by depravity of functions to which such poisoning is attributable. Neither men nor women—not even Doctors of Medicine—have ever been persuaded or compelled, to live rationally at the expense of natural or acquired inclinations or appetites, or in violation of the decrees of Fashion.

Conditions (*c*)—or the undue expenditure of organic energy, whether by overwork or the indulgence of exciting passions, cannot be interfered with to any considerable extent without encroaching upon the 'inalienable rights' of persons to an intolerable degree. Ambitious men and necessitous women will continue to exhaust their energies by untimely toil. Gamblers of all grades of respectability, will strain their faculties to utmost tension in their efforts to exchange nothing for something—whether it be to effect a 'corner in wheat' or beat a faro-bank. The libidinous will not cease to pursue their pleasures, sacrificing sleep at the shrine of Venus ; and anxious wives and mothers with saddened brows will still keep vigils awaiting the return of recreant husbands and undutiful or prodigal sons. These are things that cannot be controlled by law, nor greatly modified by education.

Conditions (*d*)—of unquestionable force and importance—preceding, and probably

involving all subsequent conditions incidental to constitutional evolution, are not sufficiently within the scope of present knowledge to be corrected by any known method of interference.

Insanity is, therefore, not only not preventable but increasing and certain to increase with the progress of civilization that, by its arts and charities, stays the relentless and remorseless hand of Nature from weeding her garden of humanity of the defective, superfluous and unprovided for.

Is this a gloomy outlook for the future of humanity? Not for him who has come to recognize humanity as a part and parcel of the universe, harmonious in its co-relations, responsive to its own necessities under all of the varying conditions of its historic development. To such only as in their egotistic infidelity and short-sightedness think that the conduct of the universe depends upon their action and apprehend immediate disaster should their schemes fail of accomplishment, is the future ever beclouded.

Thus far the strong have been strengthened by bearing the burden of the weak. When the burden shall have increased beyond certain limitations there will be a response to impending necessities, the character of which we need not now anticipate. Our duties are immediate, and pertain to whatever is nearest to be done. What we do constitutes the antecedents of sequences that we call the future; differing widely from results anticipated or predicted by those who are the conspicuous actors of any given present time or generation.

# CLINICAL LECTURES.

## PREGNANCY IN A CASE OF CURED METRO-SALPINGITIS—THE ELECTRIC TREATMENT OF METRITIS WITH LACERATION OF THE CERVIX.*

G. BETTON MASSEY, M. D., PHILADELPHIA.

This woman, aged 38, is quite an old acquaintance, having been first seen by me at Dr, Bradford's clinic at the Pennsylvania Hospital, five years ago. She then complained of extreme tenderness in the left ovarian region,so great indeed as to render her almost completely helpless. Examination disclosed an enlarged uterus with a deep laceration on one side, to its left there was a soft, irregular mass pressing the uterus to the right andvery tender. The case presented a complete picture of a latent metritis due to the laceration that had occurred five years previously at her confinement, with a more recent extension of the affection to the left tube. Shortly afterwards the case was lost sight of, and only last year I learned that the cervix was repaired later in 1888, by a surgeon of this city. This operation closed the gap in the cervix nicelybut plunged the patient into an illness that lasted more than a year, the metro-salpingitis being apparently aggravated. She appeared at this clinic about a year ago in a greatly broken condition, the tenderness and pain in the left groin being somewhat worse.

In placing her on electrical treatment it was thought best not to risk a direct treatment of the enlarged and painful womb, but begin the more tedious method of vaginal applications to the left tubal region. The negative pole of the galvanic current was used, covered with soaped absorbent cotton, with a current of about 50 ma. for some minutes twice a week. Later on in the treatment of the case several intra-uterine negative applications were tentatively given owing to the slowness of the improvement. At first she could stand but 15 ma. because of production of great pain, the current being subsequently used at a strength of 35 ma. These treatments were always painful and followed pain and were given up in favor of the vaginal applications, though I don't doubt they were of great service. To-day she is the picture of health, in spite

* A Clinical lecture delivered to students at Howard Hospital.

of some dyspepsia, and tells us that she is five months pregnant.

This case is a good illustration of the fact so frequently reiterated by me, that salpingo-oöphoritis is but an extension outwards of uterine inflammation, and is amenable to cure by vaginal applications of elictricity if the uterus is co-incidently restored to health. To restore the uterus to health will usually require this addition of direct applications of the galvanic current to the endometrium, but that these applications require some care in order that the patient's immediate condition shall not be aggravated is no argument against the method, as it gives us a mode of actual cure for conditions now almost always condemned to the knife. Even the pessimists among gynecologists, who have been removing so many of the tubes and ovaries in this condition, have recently awakened to the fact that in so doing they leave the original and an important present seat of the affection still in the pelvis within the uterus itself, and are now recommending that everything be removed at once. This association of metritis with inflamed ovaries and tubes was pointed out by myself over a year ago, and I also pointed out that in electrical treatment we have a remedy in all cases not connected with abscess formation or due to tuberculosis. To turn at once to amputation is against the dictates of reason, and incompatible with present practice in other departments of medicine.

The other case shown to you to-day, and whom we see for the first time, presents an example of a stellate laceration of the cervix of a uterus that is itself much enlarged. Some of these tears doubtless antedate the last confinement, which occurred ten months ago. Since that occurrence the involution of the uterus has been imperfect and she has had a continuous slight hemorrhage, which has not yielded to intelligent treatment at the hands of the physician. The uterus is very large and retroverted. We have here to deal with a case of subinvolution due to a hemorrhagic endometritis and a laceration of the cervix. In examining the cervix with the speculum I fail to find certain evidence of the recent occurrence of the laceration, as it is nicely healed over, just as a neglected cut in your lips would heal over with depression at one point.

It is evident that this woman suffers from the metritis and endometritis; to attribute her present condition to the theoretical influence of this healed tear is to reason in defiance of the known facts of inflammatory conditions and their pathology. This high state of hemorrhagic endometritis is of microbic origin and not due to the tear. It is, of course, possible that the laceration gave a ready entrance for microbic agencies within the uterine parenchyma originally, but that was done some time ago, and to cut out the healed scar now will not undo it.

The operation of trachelorraphy for these cases is based on pathological conceptions that antedate our present knowledge of the germ theory of disease. I shall therefore not advise that the case be treated in this way at present, but wait until the catarrhal affection of the endometrium, with its fast spreading influences within the uterine parenchyma, shall have been brought under control. If then the patient wishes this moderate rent repaired it can be done safely, though it is hard to perceive a reason for doing the operation other than the cosmetic considerations.

To cure the endometritis we have a choice of the curette or the galvanic current. Either will do it probably, though I cannot but regard the current as used here preferable for many reasons, as being a more certain and more scientific mode of altering the diseased surface to a controllable and safe extent, while also promoting absorption of effused products within the parenchyma and contraction of its muscular tissue. Several weeks treatment will be sufficient and there will be no need to use ether, have a trained nurse in attendance and make an operation of it.

It is also extremely unlikely that one curettage will suffice for this case, as there is no evidence of retained decidua as a cause of the subinvolution.

[Note.—After two applications of the positive, carbon electrode to the cavity the hemorrhage ceased. A few subsequent applications reduced the uterus to a nearly normal depth and removed the tenderness and pain.]

## CHOLERA INFANTUM AND ITS TREATMENT.*

MANUEL SEPTIEN, M. D.,† Queretaro, Mexico.

There is scarcely any disease that causes a greater mortality in childhood than that known by the name of estival diarrhœa or infantile cholera. In one single week, the last one of July of the present year, 1126 deaths occurred in thirty-three of the largest cities of England, caused by this disease alone. Statistics show everywhere a notable increase in the number of deaths during the months of June, July and August, that is to say, during the warmest season of the year. The malady is not limited to children only, but attacks also a great number of adults and old people (cholera nostras), being less mortiferous in the latter than in the former in whom it causes a mortality of 50, 60, and even 80 per cent. Only Asiatic cholera, to which it has the greatest similarity, can be compared to it for its ravages.

It is undoubtedly of microbic origin, as recent investigations have proved. It is not determined by substances of difficult digestion in the digestive tract, for it presents itself with the greatest frequency in children who take no more food than the maternal milk. Micrographic studies have revealed the presence of a special bacillus of very small dimensions and having a rounded form, and which abounds in the excretions to such a degree that in grave cases these are formed almost entirely of the organism in question, mixed with a little mucous and bacteria of putrefaction, and of amyloid bodies similar to those found in dysentery, which are probably white corpuscles altered. The bacillus is not found in the blood nor in the organic tissues; the epithelium of the kidneys is infected and degenerated, and the nutrition of the lungs suffers, which explains the brochopneumonia that is so frequently found in the autopsies. These anatomical alterations are probably the result of the accumulation of ptomaines in the blood and the rapid abstraction of water from the tissues by the abundant vomits and evacuations that characterize this disease. The exfoliation that the organism suffers is such that in a few hours, in the most severe cases the most robustchildren are turned to mere mummies.

But the energetic drainage is only the supreme effort of nature to rid the organism of the deleterious elements that poison it. To try to suppress it by therapeutical means is not an easy or a rational thing to do. It would only hinder the natural curative process. The only thing that can be done is to oppose the extreme dehydration of the tissues, by restoring to them without delay, at least a part of the water lost. This is the all important therapeutical indication, and no drug can take the place of pure cold water.

All the curative methods tried leave much to be desired. Their results are very precarious. All consist in the administration of medicinal substances, now astringents, now absorbents, antiseptics or antiperistaltics, and in the prescription of some alimental regimen. Such treatments are not in conformity with the great principle that governs therapeutics, viz., *rest of the organ that suffers.*

In the disease of which we are treating, it is very easy to act upon this great principle, seeing that the disease is of short duration, one or two days being the length of time that the gravity lasts. It is perfectly compatible with the life of an individual to suppress all food for twenty-four or forty-eight hours. Besides the condition of the mucosa of the digestive tube will not permit the absorption of any medicinal or alimental substance. The enormous exudation that is transpiring prevents all digestive and assimilative work, as the exosmotic current has drawn off all the liquids that contribute to digestion. Only the water administered to the patient in great abundance, by occupying the stomach and intestine will be able to oppose a mechanical obstacle to the pathological exudation, in turn to be absorbed by the mucosa, since it requires no digestive work, but penetrates to the

†President of the Board of Health, Queretaro, Mexico.

circulatory current by the simple act of imbibition, going to restore to the blood the water lost, and helping the skin and kidneys to eliminate the poisons that circulate through the whole body. In this physiologico-pathological consideration is founded the most efficacious curative method for infantile cholera, that proposed by Luton, of Réims.

All of us physicians who practice in Queretaro, Mexico, have employed it for many years, and we are witnesses of its marvelous results. We have the conviction of having saved by it innumerable lives, producing veritable resurrections; even we are amazed, when we find cases in a state of collapse—wasted, cold, pulseless, breathless, without strength even to cry, with the mouth dry like parchment—to see them returned to life by a simple glass of cold water. It causes amazement to see them from the moment they hear the precious liquid being poured in the glass, open their almost closed eyes and direct their little hands toward it as though they would like to snatch it from us. Then they drink away without satisfying themselves, stopping only to take breath and then on, until they drain the last drop from the glass. After a few minutes they generally vomit all the liquid they have drunk. If water is again offered to them, they turn to drink it with the same eagerness, falling directly in a tranquil and refreshing sleep. Generally they do not vomit again, and from that moment you can consider success assured.

On awakening it is found that the aspect of the little patient has changed completely. The features are already animated, the heat of the body begins to reappear and the pulse begins to make itself perceptible. This most simple of treatments which once undertaken ought not to be abandoned, consists in the absolute suppression of all food and medicine for twenty-four hours, or at the most, forty-eight hours, and administering pure cold water in abundance.

Afterwards, the only thing that remains to be done is to turn gradually to a convenient alimental regimen. A small quantity of milk is added to the water, increasing it little by little until by the end of three or four days, nothing but pure milk is given. If the complete cure is not made in this short space of time, it is a sign that the milk is doing harm and ought to be suppressed completely, substituting rice gruel, a food at the same time nutritive and constipating.

Let me strongly call the attention of this assembly to this point, the suppression of milk in cases of diarrhœa. Although the milk regimen is advised by the greatest practitioners as the most adequate in gastro-intestinal diseases, at times it is not tolerated and the evil continues in spite of the best of treatment until the milk is abandoned, replacing it by various gruels, principally of rice. This assertion is based on my already large practice, both in my own family of ten children, and in my clientele of twenty-five years.

Even the milk rendered sterile by repeated boilings, gives equally unfavorable results, perhaps for the great tendency that it has, like all organic substances, to decompose, especially in hot weather.

When once the acute period of the disease has passed, nitrate of silver in solution (5 centigrams to 50 grams of distilled water) may be prescribed, calomel in very small and repeated doses, or the most powerful antispetic that we know, bichloride of mercury in the form of Van-Swieten's liquor, six drops every four or six hours, in a mixture of equal parts water and mucilage. Opium, bismuth, and especially salol, which gives most brilliant results, will complete the treatment.

Very important details during the critical period are:—the keeping of the child in the most complete quietness, not permitting it to sit up even to vomit; giving it water in a clean sucking bottle; covering the body with blankets and placing bottles of hot water round the patient to give him heat. If any indication should present itself where it would be necessary to stimulate the heart's action, salt water injections may be given, in the proportion of 6 per 1000, in the subcutaneous cellular tissues, by means of a small exploring syringe.

A very important point, and one that should never be forgotton, is that the disease is very infectious and, for that reason, every precaution ought to be taken to avoid transmission to other children and even to adults. Contagion will probably take place by the dissemination in the air of the vomits and evacuations drying

on the cloths and contaminating the foods and drinks.

In the Mexican Medical Congress that took place last year in the Capital of the Republic, I presented a paper on the treatment of Asiatic cholera, based on the same principles I have expounded to combat infantile cholera. Happily we have not had an opportunity of trying it, but I think that if cholera should make an appearance, a trial ought to be made; more so, seeing that there does not exist any proper treatment against a disease so terrible. One half of all cases attacked (more or less) terminate fatally whatever may have been the curative method employed. Until now, only the energetic, preventive measures employed in the United States and Great Britain, have given satisfactory results.

Therapeutics are important once the disease has declared itself. The reasoning that I expounded in that medical reunion was the following: Asiatic cholera is a disease analogous to summer cholera to such a degree that they are often confounded. Both are of microbic origin, they breed in the same season of the year, and never, or very seldom, in winter. The clinical features are identical in the two diseases and the death rate is almost equal in both. If then we cure infantile cholera so efficaciously with the method that I have described, it is possible, and I believe I can say it is probable, that it may be applied to the other with equal or like success. Although they may be two distinct morbid entities, that should be no reason why it would be absurd to apply the same treatment when they have between them such a common affinity.

Typhus exanthematicus and typhoid fever, two diseases although distinct, have great analogies and are susceptible to the same treatment, and so, like this, other examples can be found.

The recent summer epidemic, which in some localities has been very severe, has served to confirm the existence of the microbe that originated it and the pathological alterations of which I spoke at the beginning.

I have the firm conviction that the American Public Health Association would do a true service to mankind if they would deign to give their high approbation to the simple method of which I have spoken, which can be reduced to the three following precepts:

1. To suppress all nouishment and medicine for one or two days.
2. To give at discretion pure cold water.
3. To return by degrees to a rational regimen.

These precepts should be recommended to the infant protective societies, nursing institutions, lying-in hospitals, etc., and, in a word, it could be made known everywhere by every possible means. This Association would only have to say the word and it would very soon be adopted in the three great countries which it represents.

## VENESECTION IN ACUTE RHEUMATISM INVOLVING THE GRAVID UTERUS.

E. M. FUREY, M. D., Norristown, Pa.

Mrs. G., born in Ireland, forty-two years of age, mother of eight children, all living and in good health, the youngest of whom is four years old. She had always enjoyed good health until early in May when I was called to attend her. She complained of nausea and general lassitude. She had been losing flesh and was much debilitated. She had menstruated but twice since the birth of her last child, the last menstruation being nine months previous, and she feared that she was pregnant. At her request I made a vaginal examination from which I concluded her fears were groundless. She had previously consulted another physician who told her at first that she was pregnant and subsequently assured her that she was not. I prescribed for her symptoms and she improved to some extent.

After a few weeks I was called again. She then complained of pains in the thighs, changing to the body of the uterus, and being prominent in the subumbilical region. The pain was greater upon pressure and the patient was confined to the bed. She also suffered acutely from a dragging sensation that

ran from the loin toward the pelvis, thence to thighs and the external genital and sacral regions. It was at this time I discovered by external examination that she was pregnant, she was probably in the fifth month of gestation for her sufferings were much increased by the movement of the fœtus. The pains were not constant, and during the remission the patient would feel quite comfortable. But when the uterus and its ligaments were attacked, there was great recto-vesical tenesmus. There was a constant desire to urinate followed by a severe smarting sensation. There was some fever and at times great thirst. I diagnosed the case as one of acute rheumatism involving the uterus and its appendages, and feared the patient would abort. Her sufferings were so intense that she demanded instant relief. In order to prevent miscarriage I prescribed anti-rheumatic treatment with little if any improvement. I then resorted to the anti-phlogistic lancet and bled the patient freely. She immediately expressed herself as being relieved of the pain as if by magic. I had at once won the confidence of the patient and her friends.

Never before in my experience had I met a case of acute rheumatism involving the gravid uterus and its appendages. Nor had I ever read of one. Yet after due reflection, considering the structure of the uterus, there should be no great surprise. Is is claimed by most authorities on the subject, that it is extremely rare. This phase of the disease has been studied by German and French clinicians, and has been ably discussed by Salathe, in a thesis to the French Academy. Most of the German authorities attribute this double recto-vesical tenesmus to a rheumatic affection that is not always exclusively limited to the womb, but which also invades the neighboring organs. That its influence upon gestation is varied and may give rise to premature delivery. The pain may be mistaken for normal labor; we may have dilatation of the os uteri, but abortion is not so frequent as might be supposed, at least this is the language of those who have made a particular study of this disease in its varied manifestations. "Its influence upon labor is to retard its progress and arrest the spontaneous expulsion of the child, and it likewise affects the expulsion of the after-birth by the irregular contraction of the organ. It diminishes the lochial discharges and the lacteal secretions, and is accompanied by acute and persistent abdominal pains which may be mistaken for peritonitis which does not exist."

The mode of treatment which was followed in this case and which gave such instant relief, is likely to be criticised by my medical brethren of the "anti-bleeder" school who like most fanatics never reason clearly because of obscured mental condition, in reference to any particular subject which they have sealed with disapprobation regardless of all the law and the facts. It is for these extremists that I have recorded this case, that they may profit by the experience of the bleeders of the present day and not be forever holding up to censure the errors only of the bleeders of all ages. In reference to the bleeders of the past, I think it was their judgement that was at fault, and this coupled with a crude physiological knowledge of remedies has brought the lancet into disrepute.

Samuel Gross used to say, "The profession is like a flock of sheep, where one jumps all follow." He also said "that when the profession gets its balance it will come back to rational bleeding." If medical history is to be believed, it seems to me the remark of the learned Professor is very pertinent, as the "balance" of the profession in general seems to have been very frequently disturbed, much to the detriment of suffering humanity. It is difficult to imagine that such men as Gross, Da Costa and that famous knight of the lancet, Dr. Hiram Corson, could have been misled in active practice for more than a half century. It follows, therefore, that rational bleeding is a therapeutical remedy of great utility and more attention should be paid to the subject by the faculties of our medical institutions. The arterial sedatives that are so highly and persistently extolled by the manufacturing chemists (who to-day seem to be striving to lead the profession), and which are also endorsed by the anti-bleeders, are of great value in many cases; but their field of usefulness is limited and they can never supplant the use of the lancet. No amount of theory can be balanced in the scale against practical experience.

## OURSELVES AS OTHERS SEE US.

S. S. TOWLER, M. D., Marienville, Pa.

Some one, I think it was Henry Ward Beecher, has said—"Many a man thinks he has religion when he only has dyspepsia, and many a man thinks he is going straight to the devil when he is only bilious."

Some things have happened now and again in the experiences of the past, that lead me to suggest in this brief paper that, more or less frequently, the diagnosis is wrong because the practitioner has dyspepsia, and the prognosis gloomy because the doctor is bilious. How often have we seen the generally bright physician mistaken in the most unaccountable manner, and how often our own ideas have undergone a complete change, without a restudy of the case or apparent cause. To-day your medical friend prescribes well and accurately, next day or next week, he mixes things up worse than a compounder of "patent cure-alls." To-day your patient or mine, is given scant courtesy and cold comfort, to-morrow, the same patient in the same condition is given attention and a hopefulness that does him a "world of good." And you and I thought on each of the separate days that we were doing the correct thing. How much was *our* stomach, and *our* liver to blame for the difference in the patient's condition from our own point of view. Is a practitioner, whose stomach is rebelling against his own foolishness, in a fit condition to judge nicely of the infirmities of his patient—Is the doctor with a torpid liver capable of making a cheerful prognosis—As a rule I don't believe he is, and I have no doubt that our own physical condition has much to do with the success of our treatment, though the ailment—personally—may be so slight as to pass unnoticed, except by the thought of, "I don't feel well."

I don't propose slopping over in a long-winded article 'analyzing' this condition, I simply want to draw attention to it "for the good of the Order," on the principle that we learn by "line upon line, precept upon precept, here a little and there a little, etc."

The great and good surgeons and gynecologists of the day, insist that personal cleanliness of the surgeon himself is of vital importance to successful operation. Let us carry the idea still further and learn that personal healthfulness—a clean stomach and an active liver—are of vital importance in the line of general therapeutics. Let us go a step further and learn for ourselves, that if we would be the educators in hygiene, etc., that we claim to be, then example must follow precept. This means that, indigestible trash, no matter how "toothsome," must be banished from our table, side-board, banquet and reception, and with it should go by all means "old Frumenti," and all his kindred spirits. It means that, *our* back yard, *our* alley, *our* vaults, *our*selves and *our* belongings must be kept consistent with our teaching and advice to others.

There is nothing new in this (more's the pity) that so little attention is paid to knowledge acquired. Hundreds of physicians have read the editorial, "The doctor and the cook." If ten per cent. of them put it in practice, there will be more stars in professional crowns than the editor ever fondly dreamed of. Said an elder in the church, "had it not been for the inconsistencies of christians themselves, Christianity would have swept the world long ago." So with "ourselves," had it not been for personal and persistent violation of our own code, we would have doubled our power for the physical good of our generation.

What student fresh from fields and woods, doomed to six hours of lectures, *per diem*, in a poorly-ventilated room, goes out of it with a clear idea of two per cent. of what has been uttered, and in my student days, woe to him if the Professor caught him napping. A recollection comes to me now, of a wag punching his sleepy neighbor in the lecture room, with his elbow and the remark, "Wake up Jim, you have just missed one of the old man's real nasty stories."

What practitioner cannot recall, (if he is honest with himself) the fact, that, his own supper was more to blame for the weary hours and his own crankiness beside the slow obstetric, than any "fool-

ishness of the patient. How many doctors blame the out-house vault for the fatal ending of the case, when their own is in as bad condition. How many "scold" the patient for undue exposure, when they, themselves have not thought enough or pride enough, to mend the soles of their own shoes. How many talk about—"no wonder she died with so much dirt in the house"—when their own office is akin to a poorly kept pig-pen. What importance can a doctor expect to be given by a patient to his directions as to "diet," while he is a persistent violator of his own rules, or what lasting impression can a professor make on his students when he, and all the rest of us in the Fraternity with him, show contempt for the advice given, at the next Society banquet.

We all have been greatly concerned that the coming medical man should be more competent than he of the present and, what with the new Examiner's Bill and improved methods of teaching in the colleges, the State Society may be fairly said to have done its duty by the practitioner of the future.

Now suppose we take a survey of ourselves and see if we cannot be more of a power for good, and advance the dignity of a great profession by personal and collective consistency.

Every thinking man knows that, no course of lectures, no matter how ably delivered; no clinics, no matter how expert the demonstration; no bedside exposition, no matter how clearly brought out, can give a man good judgment or sound common sense. But there is one thing we *can all do*, and that is this—observe our own dietetic and hygienic laws personally, and give what brains we have a chance.

Let us be *practitioners indeed.*

# SOCIETY REPORTS.

## TWENTY-FIRST ANNUAL MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION IN CONJUNCTION WITH THE INTERNATIONAL CONGRESS OF PUBLIC HEALTH.*

Inaugural Address of the President, Dr. T. H. Durgin, of Boston.

The great trust which the Association took upon itself twenty-one years ago has been worthily held, and the work to which it has addressed itself in the interest of humanity, has been diligently pursued. It is fitting, perhaps, at this time, when we may be said to have attained our majority in years, to take a restrospective glance of public sanitation, and to note the possible results of its application in the relief of human distress. The work of the sanitarian is manifold, and deals with the most vital of our personal and social interests. It deals with the air we breathe, the food we eat, the water we drink, and with the general welfare of mankind. It means the investigation of the rise, progress, and decline of epidemics, and the fostering of the growthof works and projects designed to prevent and remove the causes of disease.

The sanitarian concerns himself but little with the cure of disease. The problem which he seeks to solve is how disease can be averted. The pathologist establishes the nature of morbid processes, and his investigations suggest to us the appropriate remedy. The aim of the sanitarian is to seek out and remove the cause or causes which produced these processes. It has been said that preventive medicine embraces everything which relates to the physical well being of our fellowmen, so that it has to deal with all physical evils and, incidentally, many of a moral character. Its object is the health, and therefore the happiness and prosperity of man.

In Mexico it has been shown that sanitary science must have reached a high degree of perfection in its history. Prev

* Abstract of papers read before the Joint Sessions of the Congress, Held in Chicago, Illinois, October 10, 11, 12, 13, and 14, 1893.

ous to the conquest of the country by the Spaniards, the towns were thoroughly and efficiently supplied with water by the most perfect system; but the teachings of these early times were not permanently effective. The magnificent civil works were doomed to suffer ruin, and the world passed through dark ages of mental and physical barbarism.

The question of private or house drainage is more complex, and should be constructed only under regulations prepared by competent sanitary engineers, by plumbers who have shown their competency for such work to a proper board of examiners and have been licensed therefore. The material for this work should be strong, tightly jointed, securely trapped and ventilated above the top of the house.

In the City of Boston our private drainage, like that in most cities, is unsatisfactory, and the cause of an immense amount of inspection, complaint and annoyance, and undoubtedly the cause of much ill health. We have statute laws and city ordinances which specify the method, material and workmanship necessary for the construction of house drainage. Plans for construction and repairs are submitted to, and the work approved by, the inspector of buildings. The board of health is called upon to find defects and to order repairs, and such repairs each year number about 4,500.

For the purpose of ascertaining to what extent defective conditions of plumbing exist, and to what extent traps are supplied and water closets substituted for privy vaults, we have taken a large number of blocks of dwellings, both new and old, each season for thirteen years, and made house-to-house inspection.

The construction and care of our public and private streets have a sanitary side to be considered, especially when we remember the considerable proportion of the area of our cities which they occupy and the frequent unsanitary condition in which we find them. While the construction of streets is almost purely a matter for the engineer, the health officer has frequent cause to complain of their filthy condition. Most streets in all cities present a more or less unclean and offensive surface. This condition may be due to a faulty pavement, want of pavement or a lack of care, supported by the popular notion that an unclean and muddy condition of the streets has no appreciable effect upon the public health. Macadamized streets where much used, are unclean and offensive most of the time.

It is a common thing to find on death certificates instead of the morbid process which caused death, such indefinite information as "disease of bowels," "disease of brain," "disease of skin," "stomach disease," "ascites," "convulsions," "dropsy," "fever," "debility," "teething," "inflammation," "infantile," "heart failure," and other unlikely causes too numerous to mention, and which ought never to be used upon the records as causes of death.

In his own city, such certificates are rejected, and a competent physician sent to view the remains and consult the family or friends of the deceased for information with which to make a proper certificate.

It is to be noted, however, that information gathered in this way cannot be regarded as wholly trustworthy and often results in the statement of "unknown cause of death."

The mention of cholera, like that of smallpox, strikes terror to the people of this country, and while the deaths from these diseases are infinitely small, the fear of them has served the municipal health officers in securing almost unlimited facilities for their prevention and control, which means may be largely converted to to the care of other more common and destructive contagious diseases.

*Consumption*, the most destructive malady to the human race in our country, has received the necessary attention of the bacteriologist. He has demonstrated to us satisfactorily, the cause of the disease, the methods of its transmission, and the means for its prevention.

He is sorry to say that as practical workers in public sanitation, we have sadly neglected to apply the means which we believe would prove effectual in largely abating the prevalence of tuberculosis.

The isolation of all persons suffering from consumption, would be impracticable and perhaps unnecessary, but the use of small sputa cups containing a disinfectant at home, and bits of absorbent napkin used and securely concealed in traveling, to be burned or otherwise disinfected on returning, should at least be urged by

public health officers, and popularized as much as possible.

Earth worms it was urged bring to the surface bacilli which infect the dead body, and in dry weather they may be inhaled in the form of dust. This, it is suggested, is the reason why the health resorts of the south of Europe are centers of tubercular contagion.

Drs. Lortet and Depugnes, of Lyons, related cases of such infection, and described experiments which they made which led them to demand obligatory cremation. They mixed the sputa of consumptives in earth which they placed in pots. A month later the worms in them were tubercular, and the earth they passed through communicated the disease to animals.

Tenement and lodging houses are subjects for the constant watchfulness of the health officer, and they are too frequently found in an overcrowded and filthy condition. They are principally occupied by the poorest classes of people, including the newly arrived emigrant, whose habits of cleanliness are of the lowest order.

Turning, in conclusion, from the more onerous everyday duties of the municipal health officer to topics of greater popular interest, we find an increasing growth of public sentiment in all parts of the country favoring the municiple provision of large public parks, free public baths, small open spaces and open air gymnasiums for the enjoyment and sanitary welfare of the masses of people whose whole time is spent in the toil of our large towns and cities.

---

### REPORT OF THE COMMITTEE ON RESTRICTION AND PREVENTION OF TUBERCULOSIS.

This report was read by the Chairman of the Committee, Dr. J. N. McCormack, of Bowling Green, Kentucky. The Committee offered as its report the following conclusions and recommendations.

1st. Tuberculosis has been conclusively demonstrated to be contagious, by bacteriological experiments, by clinical observations and by a study of the history of the disease.

2nd. Tuberculosis is a preventable disease. Its preventability follows as a logical sequence upon its contagiousness, but has likewise been demonstrated in practical life.

3rd. The contagium of tuberculosis resides entirely and solely in broken down tubercular tissue. A person suffering from tuberculosis therefore does not become a source of danger to others until he begins to give off broken down tubercular tissue either in the form of sputa from the the throat or lungs, diarrhœal discharges from the bowels, or matter from a tuberculous sore such as lupus, white swelling, cold abscess, scrofula or tubercular inflammation of a joint.

4th. A person suffering from tuberculosis can be made entirely harmless to those about him by thorough sterilization of all broken down tissue immediately upon its being given off. With proper precautions it is therefore possible to live in the closest relation and upon the most intimate terms with consumptives without contracting the disease.

5th. Tuberculosis is not hereditary. A predisposition to the disease can be transmitted from parent to offspring, but this is no more true of tuberculosis than it is of all other contagious diseases.

6th. A predisposition to tuberculosis can be created anew by malnutrition or by anything which depresses the nervous system.

7th. Tuberculosis affects animals as well as man and is identically the same disease in both. In domestic life human beings and animals mutually infect each other.

8th. The media through which human beings are ordinarily infected by animals are milk and meat.

9th. Houses in which consumptives have lived and in which immediate sterilization of all brokon down tissue has not been practiced, are infected houses and are liable to convey the disease to subsequent occupants.

10th. Spitting upon floors and into handkerchiefs and permitting the broken down tissue to dry and become pulverized, is prolific cause of spreading tuberculosis.

11th. Temporary occupation of hotel rooms, sleeping-car berths, and steamer cabins by consumptives in the infectious stage can infect them so as to convey the disease to subsequent occupants unless proper precautions are taken against contamination of the bedding, furniture, and walls with broken down tubercular tissue.

We recommend the following practical measures for the prevention of the disease:

1st. The notification and registration by health authorities, of all cases of tuberculosis which have arrived at the infectious stage.

2nd. The thorough disinfection of all houses in which tuberculosis has occurred, and the recording of such action in an open record.

3rd. The establishment of special hospitals for the prevention of tuberculosis.

4th. The organization of societies for the prevention of tuberculosis.

5th. Government inspection of dairies and slaughter houses, and the extermination of tuberculosis among the dairy cattle.

6th. Appropriate legislation against spitting into places where the sputum is liable to infect others, and against the sale or donation of objects which have been in use by consumptives unless they have been thoroughly disinfected.

7th. Compulsory disinfection of hotel rooms, sleeping-car berths and steamer cabins which have been occupied by consumptives, before other persons are allowed to occupy them.

[The reports and recommendations of the Committee were adopted.]

---

TROPICAL DIARRHŒA,

by Sir Joseph Fayrer, of London, England, and read by Dr. Gihon.

This is a form of disease which is generally, if not always, the result of tropical and climatic influences, and the debility and cachexia induced thereby. It is now not infrequently observed in Europe, owing to the ever-increasing means of communication with foreign countries. It is apparently generally confined to adults, is insidious in its onset, slow in progress, and often, when not arrested sufficiently soon, fatal, owing to irreparable degenerative changes.

It has been described by many observers both English and foreign, in India, China and Cochin China, and Batavia. Most of the cases seen in this country come from China, India or Ceylon. In India it is met with frequently, where a form of it is known as "hill diarrhœa," from its proneness to affect dwellers in hill stations, especially those who have previously lived in the plains; atmospheric changes, vicissitudes of temperature, greater altitude, rarified atmosphere and possibly water being concerned in its causation. Some authors consider it a distinct disease from the white flux, which may be seen in any part of the country, but they are so much alike as to justify the belief in their identity, at all events for practical purposes. Occasionally there is a resemblance to certain forms of chronic dysentery; the two conditions may be associated or one may merge into the other.

Tropical diarrhœa occasionally makes its appearance years after the subject of it has returned from the tropics. It not infrequently begins without any previous apparent derangement of health, though it is sometimes preceded by dysentery, diarrhœa, some indication of malarial infection or functional derangement of the liver or other abdominal viscera, and is not noticed until excessive soreness of the tongue and loss of strength and wasting reveal the gravity of the condition.

*Semeiology.* This form of diarrhœa may begin with simple looseness of the bowels, or may supervene an ordinary diarrhœa or chronic dysentery. The action produces a sense of relief. The dejecta at first may be natural and bilious, but gradually becomes light-colored, frothy, pultaceous and copious. As the disease advances they are occasional tinged with blood, and the sufferer becomes more attenuated, exhausted and incapable of any prolonged exertion. The appetite may be good, but rawness and tenderness of the mouth and tongue frequently accompanied by aphthous spots and ulcerations interfere with its gratification.

*Treatment.* From the insidious character of the disease, tropical diarrhœa not infrequently gains ground before radical measures for its relief are resorted to. Successful issue depends much on the patient's resolution and perseverance in carrying out instructions. Alternations of temperature, errors of diet, fatigue or excitement, exertion, mental or physical, should be avoided. Physiological rest should be insisted on.

There is a tendency in the earlier stages to get well. The object is to favor this tendency and not thwart it by neglect of precautions. Diet it the most important consideration and must be strictly regulated and adhered to; and scarcely less important is the question of clothing, habits and mode of life.

Milk *alone* should be the only diet, and it must be given in small quantities often

repeated, say from 4 to 6 ounces every hour, day and night. Larger quantities at longer intervals will not do. When in the 24 hours an adult is able to take 3 to 4 quarts of cow's milk in this way, ample nourishment is afforded to support his strength and to enable him to recover.

This method of treatment was begun by the author before leaving India in 1872. After prolonged experience and trial of all other forms of remedies, he has found it more effective than anything. It seldom fails except in the very advanced and chronic cases, or in very aged persons. The conclusion arrived at is that though drugs are generally of little avail, if milk, taken as prescribed does not succeed, there is but small chance that any other form of treatment will do so.

---

THE SEWAGE DISPOSAL PROBLEM IN AMERICAN CITIES,

by Mr. Allen Hazen, of Lawrence, Mass.

One of the striking features of the sanitary development of American cities is the very rapidly increasing number of places which for one reason or another are treating in some way their sewage. It is not so very many years since there was hardly a sewage purification plant in the United States, while at the present time there are some thirty municipalities in a dozen different states which give their sewage a more or less thorough treatment. Of these a number are in the far West where the sewage has a commercial value for irrigation which has probably been considered quite as important as the sanitary advantages secured by the treatment, but the greater number are in the East where a dense population and increasing desire for cleanliness in the waters of streams or lakes, and particularly in water supplies, has brought to an issue problems which as yet have scarcely received the attention of the inhabitants of the less thoroughly settled states.

There are two sewage problems which are entirely different in their nature, although the same remedies may often be applied to both. There is first the pollution of rivers and lakes to such an extent that they produce a nuisance to the people who live upon their banks, and secondly the pollution of water supplies by sewage. The first case is often that of a city upon the banks of a small river which becomes so reduced in volume in dry weather that the sewage may fairly be said to be the predominating element in its composition. Up to a certain point rivers are capable of taking sewage without causing a serious nuisance to the people who live upon their banks, so long as they do not drink from them, but when this quantity has passed, deposits are formed, decomposition sets in, and the stream is rendered foul in appearance and objectionable in its odor. The exact quantity of sewage which can be mixed with water without causing a nuisance varies with local conditions and can only be approximately estimated, but as long as the limit is not passed, and the bodies of water not used for drinking, the disposal of sewage by turning it into such water is entirely unobjectionable and by far the most satisfactory method possible.

Where the sewage of a town is entering the public water supply of a neighboring town, or worse yet, its own supply, the problem is entirely different. The removal of the organic matters of the sewage becomes of secondary, although still an important matter, while the removal of those germs of disease, which would otherwise work such mischief among the consumers of water, becomes the one important point.

The author then dwelt upon the possibility of sewage treatment by chemical precipitation, which he said was the same the world over. Local conditions are only of secondary importance.

The experiments undertaken by the Massachusetts State Board of Health at the Lawrence Experiment Station some six years ago, indicated that the local conditions in Massachusetts would allow the treatment of sewage upon land with even more favorable results both as to quantity of sewage treated and quality of effluent obtained, than had been supposed to be the case from a study of European practice.

It is impossible by any combination of chemicals to secure the purification which approaches even remotely the result obtained by land treatment, but when the problem is simply to keep the water into which the sewage flows reasonably clean, the result with careful manipulation is quite satisfactory. When, however, the treated sewage finds its way into the source of the public water supply, the effluent produced by even the most com-

plete chemical precipitation cannot be regarded as an entirely unobjectionable addition, and such water should be further treated by filtration before use.

---

THE COLLECTION AND DISPOSITION OF ANIMAL AND VEGETABLE WASTE IN THE CITY OF MILWAUKEE,

by Dr. U. O. B. Wingate, Commissioner of Health of Milwaukee.

As early as 1879, the city of Milwaukee began to grapple with the garbage problem, and it has been a long and serious struggle until a recent date. In the winter of 1891, and 1892, the State Legislature passed an act authorizing the Common Council of the city to enter into a contract for the disposition of garbage, with the advice of the Mayor and the Commissioner of Health. It was decided to let the contract for five years to a company who would build a plant fourteen miles out of the city, collect and remove to said plant all garbage, offal, dead animals, both great and small, and animal matter in the city of Milwaukee, including refuse matter from commission houses, etc., to said plant, in which they would dispose of it in a sanitary manner. This contract went into effect and the work was commenced in June, 1892.

The Company constructed a plant at an expense of some $110,000. They purchased a powerful steam barge for transportation; they put on fifty steel, air-tight tank wagons for collection, and two large covered wagons for the collection of large dead animals. Since the first of September, 1892, the plant has been in operation to the satisfaction of the city officials of Milwaukee, creating no nuisance or stench whatever that can be reasonably objected to in its location, and the collection and transportation of the material during that time has been fairly satisfactory.

DISPOSAL OF GARBAGE AND WASTE OF WORLD'S COLUMBIAN EXPOSITION,

by Col. W. F. Morse, of New York.

Since the meeting of the American Public Health Association two years since, marked progress has been made in the destruction of garbage and waste of cities by fire. Six years experience has shown this method to be of far greater value than any other, and improvements in furnaces and reduction in cost of operation have steadily made it more popular and useful.

England has now furnaces in every large city and the number is yearly increasing. This country is awakening to the value of this method, and it has been inspected and recommended at a great number of places. The most striking and effective work done in the world is at the World's Fair, where two furnaces of the Engle Sanitary Company have been at work since the first of May.

It was early seen that the sanitation of the Fair, the care of the health of the great multitudes resident and who would come as temporary guests, would demand the best, and only those which had been thoroughly tested, methods of providing for the drainage, and the collection and disposal of the great mass of daily accumulating garbage and organic waste. After the drainage was arranged, the question of sewerage disposal and garbage destruction came up. A contract was made with the Engle Sanitary Company of Des-Moines and New York, for two garbage cremators to burn 100 tons of sewerage sludge, garbage and stable refuse. These two furnaces were built in the Fall, and at the opening of the Fair were ready for work. They are in the extreme southeastern part of the grounds, near the Forestry building, back of the power house of the Intramural Railroad, employing the well known device of the Engle Company, two fires, one at either end, the one burning the mass of garbage on the grates, the other destroying the smoke, gases, and all results of this combustion. These furnaces have been in constant work every day since May 5.

The garbage is brought at night from 11 to 8 o'clock A. M., and placed at once in the furnaces. From 25 to 40 loads each of one ton, having sometimes ashes or water in large amounts mixed therewith. Everything goes into the furnaces, four horses, two camels, cows, deer, elk, pigs, goats, dogs, etc., all follow the same road and are burned with equal ease. No results can be seen from the chimney. A thin, invisible, carbonic acid gas, discharged at a temperature of 1000 degrees is all that results. No smoke, no odors. nothing that can be offensive is detected, Though in daily use an observer would not know any work was done, unless he

came to the building. At 10 A. M. the loads of sewerage cake begin to come. This is a thick, heavy, soggy, mass of lime, foecal matter, paper pulp, etc., with 60 per cent. of water mixed. The quantity varies from 10 to 18 or 25 tons, and is the most refractory material to burn yet found. The fires are oil fed by jets of air, a pressure of 12 ounces of air doing the same work that is done in the boiler house with 120 pounds of steam. The ashes are used by Exposition people for filling low places, though they have a value of $10 per ton for fertilizers.

There are six burners spraying oil, the whole using 37½ gallons per hour. The cost for fuel and labor is from 75 to 85 cents per ton for sewerage sludge and 50 to 70 cents for garbage.

At other places where these same furnaces are used, the cost is reduced by bringing to the furnaces the paper, sweepings, and all kinds of city combustionable waste, which makes fuel to burn wet matter, and reduces the cost 12 to 15 cents per cubic yard or 30 to 40 cents per ton.

Official reports from Savannah were read showing the cost for last eight months to be 11 cents per cubic yard.

The work has been continuous, no stoppage, no nuisance, performed under observation of thousands of persons, inspected by many interested in this work from abroad, and has met with deserved credit and favor from the Board of Administration.

By adoption of similar furnaces at four points in Chicago the whole garbage nuisance could be abolished, the same work done for the city that is here performed, at a reduced cost, and the vexed problem of garbage disposal settled and got rid of once for all. This is no theory or experiment. This company was asked to do this work because they had demonstrated elsewhere their ability. There are forty furnaces or more built by the Engle Company and in successful operation, more than twenty times as many as have been built by others, but this is the most successful instance of the destruction of garbage on a large scale that has been seen in this country.

HOW CAN WOMEN PROMOTE PUBLIC SANITATION?

by Dr. Sarah H. Brayton, of Evanston, Illinois.

As instructors in hygiene, nurses have a wider scope for sanitary reform than physicians, living as they do with the families they attend their opportunity for the diffusion of knowledge is greater. Undoubtedly there is much that women could do on health boards; there is more that they *must* do among their own sex to increase the sum of sanitary knowledge among all classes and promote intelligent cooperation with health authorities whoever they may be.

THE PROGRESS OF SANITARY KNOWLEDGE AMONG THE WOMEN OF ENGLAND,

by Lady Prestly, of England, read by Mrs. Henry Wade Rogers, of Evanston.

The author of the paper went back 20 years when she first joined the Executive Committee of the National Health Society, and attended the meetings in a small, dingy, draughty room in a house about as unsanitary as any to be found in London, and traced the progress made in sanitary science from that time to the present. The author would impress upon all mothers and those who are responsible for the welfare of others, the desirability of giving personal care and forethought, which alone can avert the consequences of unsanitary surroundings.

NOTES ON CHOLERA AND ITS MANAGMENT IN HULL, ENGLAND,

by Dr. John Wright Mason, Medical Officer of Health, in Hull; read by Dr. Charles N. Hewitt of Minnesota.

The first epidemic of cholera occured in 1832, but the total number of deaths from the disease did not exceeded 270.

On the 10th, of August, 1849, the great visitation of the disease commenced. The total number of cholera and diarrhœa victims during the invasion was 1860, being one in forty-three of the whole population of 11,000. Six hundred persons died from cholera alone in one week in September. The average age of the victims was from 30 to 36 years of age. Of the total number of deaths recorded, seventeen hundred and thirty-eight belonged to the laboring classes and one hundred and twenty-two to the wealthy. The greatest mortality occured in those parts of the town where the levels were the lowest, and in which the unsanitary surroundings were the most noticable. It is recorded by an eminent minister that

on one day—black Sunday—he himself interred no less than 43 bodies of his fellow citizens. The water supply was at that time obtained from the stoneferry waterworks, situated one and a half miles from Hull and two and a half miles from the mouth of the river, the water being obtained from the river Hull, the widespread character of the epidemic being greatly attributed to the impurity of the river water. Since 1846, Hull has increased both in wealth and population, and its area has been considerably extended. The number of emigrants passing through the port en route for America has averaged between 50,000 and 60,000 yearly during the past ten years. The infectious diseases (notification) act, 1889, has been applied to the port as well as to the urban authority. Measles was included amongst the notifiable diseases on the 10th of February, 1893.

Cholera follows the line of international communication, and with the modern increased facilities for rapidity of transit, so is the danger of its possible invasion increased by emigration or otherwise. England does not depend upon the false security of quarantine, but rather upon its sanitary administrations, and each district should be in such a state of sanitary preparedness that the disease if imported should not spread. The experience of 1892, during the epidemic at Hamburg, in those parts which are exposed, and possibly none more so than the port of Hull which was in daily communication with that cholera stricken city, must have inspired confidence in the public mind in this country and the continent of Europe, that medical inspection, the due regard for the rigorous inspection of all articles likely to convey infection, improved sanitation and efficient hospital equipment, were alone sufficient to arrest the progress of the disease. Our first line of defense against the introduction of cholera consists of the medical inspection upon arrival both by day and night, of all vessels from cholera infected or suspected ports, and should cholera have developed during the voyage amongst any of the passengers or crew, the removal of the patients to hospital and the isolation of suspected cases, and the detention on board the vessel of such persons who may be in a filthy or otherwise unwholesome condition, and who cannot satisfy the medical officer of health as to their place of destination.

The second line of defense against the possible introduction of cholera, or other diseases, should be well protected, and the early preparations against the means by which such diseases if imported, spread, should be studied, thought out and perfected in the interim, and not during epidemic prevalence and excitement. Special attention should be directed towards a pure and unpolluted water supply, the periodical and regular removal of all excreta and refuse matters in the midst of populations, the frequent flushing of all drains and sewers, the prevention of over-crowding, the systematic inspection of common lodging houses, and lastly, but not least, our food supplies.

Hull is essentially a privy town. The death rate of Hull from all causes for the ten years 1882 to 1891, averaged 20.7 per thousand. The death rate from fevers during the same period was equal to 1.26 per thousand, and for diarrhœa alone 1.10 per thousand.

The author then dwelt upon the management of cholera. The precautions which are adopted in Hull of what has been described as "the movement of a sanitary column," are as follows:

Immediately upon the receipt of a notification of cholera, or of sudden illness of a choleraic character, either by the medical practitioner in attendance, the sanitary inspectors or the police, the medical officer of health is communicated with and immediately visits the case, or in his absence his assistant. Should the case admit of removal, the horse ambulance, fully eqipped with trained men in attendance is immediately requisitioned by telephone. The assistant inspector of nuisance for the district in which in which the case occurs is forthwith acquainted and makes his appearance with a column comprising flushers, lime washers and disinfecting staff. He superintends the removal of the inmates of the house to hospital for the purpose of bathing and the disinfection of their clothing, the disinfection of the house, together with all articles of bedding, clothing, etc., which has been exposed to infection, and the destruction of such articles as may be ordered by the medical officer of health or his assistant.

The contents of the privy are removed to the destructor for cremation and the interior cleaned, disinfected and lime washed. The subsidiary drains in the immediate contiguity of the house are thoroughly flushed, and disinfectents are freely distributed in the neighborhood of the outbreak.

---

TUBERCULOSIS AND THE FOOD SUPPLY,

by Dr. D. E. Salmon, Chief of the Bureau of Animal Industry.

The author assumed without argument, as already established by scientific investigation, that tuberculosis is a parasitic disease, that it is caused by the multiplication of a specific micro-organism in the tissues of the animal body and by no other means. Of the two methods by which the disease is contracted with man as well as with animals, it may be admitted that the most frequent and, therefore, the most important, is the inhalation of the micro-organisms suspended in the inspired air. The speaker had no means of estimating the proportion of cases of tuberculosis which arise from infected food, but he was prepared to admit that tuberculosis of the abdominal organs and tubercular meningitis, particularly of children, were generally caused in this way. The author then considered infection through the milk supply and infection through the meat supply. Tuberculosis is one of the most common diseases of milch cows. It exists in many dairies, and may affect 50, 75 or 100 per cent. of the animals in large herds. We do not know the average proportion of cows infected in this country, but in the dairies around our large cities from three to five per cent. have been infected when diagnosis was made by the ordinary methods of examination. In the United States we have no statistics of the results of the tuberculin test except with herds known to be tuberculous. Fortunately, the milk from all tuberculous cows does not contain the bacilli. When there are tubercles in the udder, however, the milk may contain immense numbers of these germs, and this is particularly the case if the tubercular mass softens and its contents escape into the milk ducts? The milk from cows so affected must be considered an extremely dangerous article of food.

The prevalence of tuberculosis in dairy cows can be lessened and the danger from infected milk diminished by a careful and periodical inspection of the herds from which the milk supply is obtained. This inspection must consist not only of a physical examination, but must also include the tuberculin test. There must in addition be some means provided for securing the destruction of animals found to be tuberculous.

---

SYPHILITIC INFECTION AS A VEHICLE OF THE COMMUNICATION OF TUBERCULOSIS,

by Dr. Manuel Carmona y. Valle, of Mexico.

The author of this paper cited the history of a case demonstrating the possible association of the syphilitic virus with the pathogenic agent of tuberculosis, and the possibility of transmission not only of the syphilis but of the tuberculosis also. He had found in the ulcerations of the throat both characters.

---

THE INFLUENCE OF HABITATIONS IN THE PROPAGATION OF TUBERCULOSIS

by Dr. Manuel Gutierrez, of Mexico.

Pulmonary tuberculosis is more frequently observed in the United States than in the Republic of Mexico. The statistical records give a proportion of from 118 to 120 per thousand in America, while in sunny Mexico it does not reach the number of 60 to every thousand. One of the causes which contribute to produce so notable a difference in the propagation of so dangerous a disease, is the difference of the elevation in both countries, because we know that dry air is not a vehicle for the multiplication and generation of the bacillus of Koch and the relative rarefaction of the air is in a direct ratio to the elevation. Mexico being 2257 meters above the sea level, it is consequently not difficult to explain its superiority in arresting the conditions favorable to the propagation of a disease which undermines so many constitutions.

The author's attention has been called to the fact that not only in the hotels and public establishments, but also in private dwellings in the United States, there are rooms constantly illuminated with artificial light and in which the light

of the sun never penetrates. The individuals who work therein are deprived for many hours of the beneficial action on the economy that we know solar light exerts, and we know that this privation and the special conditions that accompany it can contribute to the development of tuberculosis by producing (1) the anemia and its consequent state of malnutrition, preparing the ground that serves for the cultivation of the germs of the disease; (2) Increasing considerably the temperature of the place illuminated, constitutes also a propitious cause of multiplication of the pathogenic principles involved in the tuberculosis process.

---

PROPHYLACTIC AND THERAPEUTIC VALUE OF FOOD,

by Mrs. Ellen H. Richards, of Boston.

The prophylactic value of food is to keep the human body in a high condition of health. The main object to be gained is to establish a higher standard of health in the community, to make as widely known as possible the fact that most of the ill-health now prevalent is needless; that a little self denial, a little more attention to the rules of hygiene, a little more living in the open air would cause a large number of the diseases now so common to disappear.

---

HYGIENE OF HAIR DRESSING AND BARBER SHOPS,

by Dr. Angel Contreros, Pueblo, Mexico.

The disease which persons are most liable to contract in barber shops is scurf, and the author therefore touched on what appeared to him the most important points in the consideration of this matter. Scurf is understood to be a disease of the capillary system caused by the presence of vegetable parasites. The disease can be transmitted by some animals which already have it; but the contagion most commonly takes place from person to person; and in families, in educational establishments, and in barracks the disease assumes an endemic character. Several times the center of this propagation has been found in a hair dresser's or barber's shop and has arisen from the use of instruments which have been badly cleansed. Barbers and hair-dressers ought therefore to be very careful in cleansing the utensils which have served for one person before they are employed on another. All the utensils should be subject to the action of heat for a space of ten minutes in a vessel or receptacle at a temperature of 120 degrees, and the razors in an oil bath.

---

THE WATER SUPPLY OF CHICAGO, ITS SOURCES AND SANITARY ASPECTS,

by Arthur R. Reynolds, M. D., Commissioner of Health of Chicago, and Mr. Allen Hazen.

The extensions of the various tunnels within the last two years have undoubtedly secured for the city a water less liable to sewerage pollution than was formerly obtained. The available analyses of the water are perhaps inadequate to measure accurately the improvement, but fortunately we can apply that most satisfactory of all water tests, the typhoid fever death rate. The improvements in the water intakes have not all been made at a single date, but if we compare the two years ending September 1892, and September 30, 1893, we find that during the earlier years the shore intakes at Lake View and Chicago avenue were in common use while the four mile tunnel was not yet opened, while for the greater part of the latter year the shore inlets were entirely closed and the four mile tunnel and the one mile tunnel at Lake View were in use. For the year ending Sept. 30, 1892, the number of deaths from typhoid fever in Chicago was 1,790 in total of 26,646, or a percentage of 6.72. For the year end-September 30, 1893, deaths from typhoid fever were 712 in a total of 26,977, or a percentage of 2.64. It is most unfortun- for this comparison that the old supplies were partly in use during the first few months of the latter year, before the four mile tunnel was opened. We may believe that if this had not been the case the comparison would have been still more favorable to the improved supply. It is a well know fact that people using a water supply to which they are not accustomed are often more susceptible to any infection which it may contain in than are those using such water regularly. A striking illustration was furnished by Philadelphia in the Centennial year, when the typhoid death rate was nearly doubled, while in Chicago the present year for the first five months of the Fair period the

rate has been less than half as high as for the corresponding month of the preceding year, and for the entire year under consideration, in spite of the vast numbers of visitors continually present, there has been a reduction of over 60 per cent. in the typhoid fever death rate. This reduction is most striking, and it can hardly be doubted that the improvements in the water supply have been the chief if not the only cause. As there is no marked local distribution of the typhoid fever, so there were no exceptions to the general improvement with better water supply. Not a single ward but showed a substantial reduction. Stronger evidence could hardly be produced to show the casual relation between the contamination of the water supply and typhoid fever. The mortality percentages from typhoid fever in a number of cities may be compared as follows: Chicago, 1892, 6.72, in 1893, 2.64; Philadelphia, 1892, 2.22; Boston, 1.22; Paris, 1.01; New York, .90; Brooklyn, .80; London, .49; Berlin, .42. The cities having the lowest typhoid fever death rate, London and Berlin, use only filtered water. London draws nearly all of its water from the two grossly polluted rivers the Thames and the Lee, and, after filtering it, supplies it to a population that is almost free from typhoid fever. It may be a question worth considering by the engineers whether filtration would not be as cheap and effective a means of improving the water supply as the farther extension of the tunnels.

---

REMOVAL OF PATHOGENIC BACTERIA FROM DRINKING WATER BY SAND INFILTRATION,

by Mr. George W. Fuller, of Lawrence, Mass.

That drinking water is a carrier of some diseases there can be no doubt. Numerous laboratory experiments by many investigators indicate that the bacteria generally attributed to be the specific organisms of typhoid fever, Asiatic cholera, and other diseases live in water for many days. The results of long-continued investigations at the Lawrence Experiment Station show that the typhoid bacillus is able to live in the water of the Merrimac river, in greatly diminished numbers, for a period of at least twenty-four days. Other investigators, using different water and different conditions, estimate the length of life of this germ at from three to eighty days. The duration of life of the cholera spirillum in various waters has been observed to be from two days to seven months. Modern hygiene demands that drinking water shall be free from pathogenic bacteria, and the means by which such water can be obtained are worthy of our most careful consideration.

During the past forty years many filter plants have been constructed in Europe and numerous experiments in the filtration of water have been made particularly during the past decade. This is largely due to bacteriology which enables us to determine the actual efficiency of filters with regard to the removal of bacteria. The operation of many filters is quite satisfactory, as is shown by the low death ratio from those diseases conveyed by drinking water and by the results of numerous bacterial analyses.

In summing up our present knowledge upon the removal of pathogenic bacteria from drinking water, we may state that in addition to the experience of certain European cities, the Lawrence investigations, covering a period of more than five years and including the bacterial examination of more than eleven thousand samples of water, indicate that it is entirely practicable to construct filters that will economically purify and remove more than ninty-nine per cent. of bacteria which may be present in the unfiltered water.

---

AN EXPERIMENT IN DISINFECTION. HOW AN EPIDEMIC OF PNEUMONIA WAS CHECKED,

by Dr. Jerome Cochran, of Birmingham, Ala.

The paper dealt with an epidemic of pneumonia checked by disinfection. The total number of cases during the epidemic was 93 ; total number of deaths 30, nearly one-third of the cases. The epidemic occurred in the prison at Pratt Mines, Alabama. The prison was divided into three sections, and while the disinfection was going on in one section the conoicts belonging to that section were crowded into the other two sections. The mattresses were taken off, and these together with the blankets were scattered over the floor. Then by means of a force pump and a long hose pipe the ceilings, walls,

and the floors with their contents were literally deluged with a solution of bichloride of mercury, 1–1000, until the bichloride solution stood in puddles and ran in rivulets on the floors. The mattresses, etc., were turned over so as to be wetted as thoroughly as possible on both sides. Dr. Cochran has more confidence in the disinfecting power of heat than in the bichloride. The mattresses, blankets, etc., were therefore put into large steam chambers that had been constructed for the purpose and kept there for six hours, after which they were taken out and dried. In the mean time the disinfected wards were thoroughly scrubbed out, whitewashed and fitted up so that they could be occupied again the next day. The convicts, before they were returned to their old quarters, were required to take a bath and put on clean clothes. In one week the epidemic, attacked at the period of its most rapid increase, went out like a fire under a deluge of water.

---

A CONTRIBUTION TO THE STUDY OF YELLOW FEVER FROM A MEDICO-GEOGRAPHICAL AND PROPHYLACTIC POINT OF VIEW IN THE MEXICAN REPUBLIC,

by Dr. E. Liceaga, President of the Superior Board of Health, Mexico.

The author presented the following conclusions :

1. The places where yellow fever reigns and which can be considered as centers of infection are in the Gulf of Mexico, Vera Cruz, Frontera, Campeche and the Districts on the northern coast of the Yucatan Peninsula, the last named separated by the Yucutan canal from the Island of Cuba, where the fever also reigns. On the great Pacific Coast, which belongs to the Mexican Republic there is not a single yellow fever center.

2. All the Mexican territory on the Gulf of Mexico and on the Pacific Coast is well adapted for the disease when imported.

3. Yellow fever has become epidemic in the following places of the coast on the Gulf : Matamoros, Altamira, Tampico, Tuxpam, Papantla, Misantla, Nautla, Alvarado, Goarzavoalcos Minatitlan Lagang and San Juan Bautista de Tabasco.

4. The epidemic has extended into the interior, but never into places situated more than 1008 meters over sea level.

5. On the Pacific there is not a yellow fever center, but it has been imported into the following places : On the Peninsula of Lower California, La Paz y Todos Santos ; on the Continent, Guaymas, Altata, San Blas, Mansanillo, Santiago, Acaponeta, Puerto Angel, Salina Cruz, Tonala Soconuzco, Tapachula and San Benito, and in the interior in Hermosillo y Culiacan.

6. Immunity against yellow fever is obtained after having had the disease in any of its forms. It is possible that this immunity may be lost at times, but it is seldom the case as it happens with typhus, small-pox and scarlet fever, which may be had by a person who has had them.

7. The Vaccine of Jenner against small-pox and others which science has discovered, authorize us to look for the one that will prevent the yellow fever. The inoculations against this fever which Dr. Manuel Caramona y Valle has practiced with success should be tried on a large scale, in an uniform manner, in order to be able to find out if they are efficacious. If experience confirms it, then they should be made compulsory in the countries where the fever reigns. If they should not prove worthy, then the inoculation of blood serum, as proposed by Dr. Sternberg, from persons enjoying immunity, should be tried on a large scale and in an uniform manner.

8. The purification of the drinking waters used by persons who have to expose themselves to contact with the disease, should be recommended. The purification of the water used on board the ships leaving or calling at infected ports should be proposed.

9. The sanitation of the places which are yellow fever centers should be done at once.

10. To prevent, by means of sanitary police measures, the importation of fever into places where it can be developed.

---

HOW SHALL OUR LEPERS BE CARED FOR?

by Dr. Benjamin Lee, of Philadelphia, Pa.

The State Board of health of Pennsylvania and the Board of Health of the city of Philadelphia have had some unpleasant experiences with lepers which had led both of these bodies to appeal to the general government to establish a colony or

colonies, where these unfortunates might be provided with the comforts of home and medical care and nursing, and at the same time cease to be a menace to the health of those with whom they were thrown in close contact. The United States had only gone so far as to make the affection quarantinable at the seacoast and to order those found suffering from it on arriving vessels to be at once returned to the ports from which they came.

---

The American Public Health Association elected the following officers:

*President*—Dr. E. P. La Chapelle, of Montreal.

*First Vice-President*—Dr. Manuel Carmona y Valle, of Mexico City.

*Second Vice-President*—Dr. J. N. McCormack, of Bowling Green, Ky.

*Treasurer*—Dr. Henry D. Holton, of Brattleboro, Vt.

*Permanent Secretary*—Dr. Irving A. Watson, of Concord, N. H.

*Place of next meeting*—Montreal, Canada, October, 1894.

*Note.* Although the gathering was denominated an International Congress of Public Health, very few outside of the members of the American Public Health Association contributed to the proceedings. The bulk of the work was done by the members of the Public Health Association.

---

Moral Immunization.—Our associates in mind will appreciate the golden words emitted by the great German scientist, Prof. Virchow, in his lecture before the Royal Society in London, and which we give here without commentary.

"Who among us, he said, is not in need of friendly encouragement in the vicissitudes of life? Fortunately, real satisfaction is not derived from the applause of others, it resides in our own consciousness of honest work performed. How otherwise could we remain firm in the assaults of daily life? How could we preserve the hope of progress and final victory in the face of our opponents' attacks and of all the insults never spared to any one who shares in public life? He who has been exposed during a long and active life to public opinion, will certainly stand at last unjust criticisms with equanimity, but this is only the result of a firm faith in the goodness of our cause and in its final triumph. This is our hope in our struggle for the progress of science and art; this is our hope in the struggles for civil and religious liberty; and in this hope we become inured to malevolent attacks. It is a kind of immunization which, I admit, has its great inconveniences, for this hardening to unjust attacks may easily produce a similar indifference to just criticisms, and even more: as a result of the tendency toward contradiction inherent to the human mind, it may lead to indifference toward praise and acknowledgment. Our mind retires within itself, very often dissatisfied with the world and with itself. For who is so much above all attacks that a faint acknowledgment of the justice of the attacks of our opponents should not penetrate the hardest armor of the most obdurate self-esteem? Happy the one who has strength enough to maintain or recover his relation to his fellow-men and to participate in our common labor! Three times happy he who in this task is not missing the acknowledgment of competent fellow-workers!

Thoughts of this kind were filling my mind when with a view of the present occasion I look at my own life and at the history of our science—or, in other terms, the history of our predecessors. How often I found myself in a condition of pusillanimity with a pronounced feeling of depression. And in the history of science itself, what long periods of stagnation, what long interruption it has suffered from the triumph of errors! What saved me, was the habit of work which I never renounced even in the days of external misfortunes, the habit of scientific activity which always appeared to me as a recreation, especially after tiresome and fruitless efforts in political, social and religious fields.—*Ex.*

# The Medical and Surgical Reporter

ISSUED EVERY SATURDAY

ADDRESS

Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D., Editor.

RODERIC C. PENFIELD, Publisher.

PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, OCTOBER 28, 1893.

## EDITORIAL.

### THE PAN-AMERICAN MEDICAL CONGRESS.

For years past American physicians and surgeons have neglected the opportunities, turned their backs upon the schools and clinical advantages of their own country and hastened across the water to sit for a few months at the feet of some *privat docent* whose language they *did* not understand and whose name they even could not pronounce correctly. This apparent lack of respect for and confidence in the institutions of their own country has naturally had a lowering effect upon the estimation in which we are held by citizens of our sister republics of Mexico, Central and South America. More unfortunate still was the fact that those who yearly went abroad for post-graduate study seemed to think that in order to show the great advantages occurring from a course of study in foreign schools it became necessary to decry those of their native land. A species of toadyism not confined to medical men.

The nations of the south not being as well developed as the United States were compelled to send large numbers of medical men abroad in order to secure that culture so necessary to a great or useful medical career. These students might largely have been brought to our shores had our institutions been properly appreciated even by ourselves. But finding that New York, Philadelphia and Chicago were ignored by their own inhabitants and a system of foreign worship inaugurated in every medical center of this country, they naturally turned their footsteps toward Paris, Vienna and Berlin.

Thus year after year have we missed the golden opportunity of planting a host of graduates from our best schools in the midst of our cis-Atlantic sister republics.

Foreign worship and French and German toadyism are not now rampant as in years gone by. It is even conceded by the worst of anglomaniacs that it is possible for one to get a finished medical education in America. Our great post-graduate schools in Philadelphia, New York and Chicago are opening to yearly increasing classes and their practical teaching is filling the country with a host

of practical men, whose increased knowledge and power make their services of immeasurable value to their friends. The prodigals who return from Vienna and Berlin find men educated at home very often much their superiors, and often they have to supplement an incomplete and imperfect course abroad by better instruction and more favorable opportunities at home.

We have long needed a great meeting of some kind to present ourselves medically to the nations of the South. Thanks to the energy and patriotism of Dr. C. A. L. Reed, the great Pan-American Congress furnished us the long needed and much desired opportunity. Our best schools and our best men are now thoroughly known in the distant republics of this continent, and we will be greatly disappointed if the knowledge does not lead to a great influx of students out from home in search of post graduate study. Surely they who went through the halls and over the grounds of the University of Pennsylvania, saw a school which for thoroughness of equipment, severity of curriculum, facilities for teaching and number and enthusiasm of yearly matriculants cannot be surpassed if equaled in any city of Europe. If we neglect not the advantages which this Congress and the World's Fair give us, students instead of going from will be coming to us.

Our surgery and gynecology and our obstetrics have already become so successful that the great operators of the old world are ashamed to quote beside it their own statistics, and it has long been recognized and admitted that unless one wishes to study pathology, everything that can be taught of lifesaving measures is here taught better and by better men than in any capital of Europe.

## BACTERIOLOGICAL NOTES.

### PATHOLOGY AND ETIOLOGY OF DIPHTHERIA.

Klein, in the supplement containing the report of the Medical Officers Local Government Board, London, 1891–1892, continues his investigation of diphtheria. The work of the past year appears to have been directed toward the pathology of the disease with special reference to the differentiation of it from membraneous croup of the larynx and trachea which are frequently associated with and indeed, derived from, membraneous diphtheria of the tonsils and pharynx. Besides these there are cases of membraneous croup of the larynx and trachea which seemingly are not connected as regards time and place, with diphtheria. The author proceeds to discuss the nature of diphtheria, its definitions, and cause. He considers the Klebs-Lœffler bacillus as, without doubt, the cause of the disease, and considers it of diagnostic value. This is in accord with the results of other investigators. Klein proceeds to discuss several cases of true diphtheria with croup and with scarlatina. He found streptococci in considerable numbers associated with the diphtheria bacillus in one case. From his investigations he draws the following conclusions:

1. "Membraneous croup of the larynx and trachea occurring concurrently with diphtheria of the fauces, is *true* diphtheria."

2 "The so-called scarlatinal diphtheria is not true diphtheria."

3. "Diphtheria of the fauces, as also membraneous croup, following some time after scarlatina, are both true diphtheria."

4. "Membraneous croup of the larynx and trachea without diphtheria of the fauces, may be of two kinds:—(a), true diphtheria (he cites case five in his investigation as an example); or (b), genuine fibrinous croup without presence of the diphtheria bacillus and therefore not true diphtheria."

## THE IMPORTANCE OF THE SPLEEN IN THE PRODUCTION OF IMMUNITY AGAINST TETANUS.

Tizzoni and Cattani have conducted some very interesting experiments in which they have shown the importance of the spleen in the production of immunity against tetanus in rabbits. Although they could produce resistance in normal rabbits they could not in those that had had their spleens removed. In a more recent paper the authors have added much to the knowledge of immunity against tetanus. With the vaccine which they now have they can produce immunity in rabbits with two injections, the first of five cc, and the second of ten cc. With this vaccine they can render spleenless rabbits (spleens removed eight to fifty days previously) quite as unsusceptible to tetanus as normal ones, and the serum from these rabbits had as marked an immunizing effect as that from control vaccinated rabbits. These results are in accord with those of Orlandi in the case of rabies and by others in case of various other infections but they are contrary to the results first obtained by Tizzoni. At first quantities of immunizing serum which while they were able to protect healthy animals failed sometimes in animals that were weakened by bleeding or disease. In the present or later work, the material was much more powerful and it was also used in large doses.

From the above briefly mentioned results the authors conclude that removal of the spleen, in as much as it modifies the general process of nutrition, may have a certain influence on the development of immunity, an influence which makes itself known when material of limited power is used for immunization: but that the spleen in itself takes no part, direct and necessary, in the process of immunization itself, and that if the substance which actually produces immunity is a product of the animal organism and not the substances actually injected, which seems, however, in the light of recent work improbable, its formation does not take place in the spleen or at least in this organ exclusively. The authors think that the same fallacy led to the mistake of Foas assistant, Cesaris-Dunel who considered that the spleen played an important part in the production of immunity against pneumonia, a result contradicted later by Foa (*British Med. Jour.* Sept. 16, 1893) [In a subsequent number we hope to give a list of several cases of tetanus that have been cured by the use of serum from immunized animals.—Ed.

## DISEASES DUE TO STREPTOCOCCI.

In the *Centrablatt f Klin. Med.* August 19,1893,is an interesting article by Goldscheider on the streptococcus. He states that the pathogenic effect of this organism is due, at least to a great degree, to the accompanying conditions of invasion. It is a question whether severe streptococcus infections as in puerperal septicaemia or pyæmia or the pyæmia of diphtheria, are due to an especially virulent streptococcus or whether less harmful organisms are capable of developing more virulent properties. The investigations of the author are led to the conclusion that biological conditions of the animal body are of much importance in regard to the character of the disease produced. Clinical observations have shown that where necrotic tissue is present there is a special tendency to streptococcus diseases. These conditions were imitated experimentally by the author, when putrid cultures of streptococcus were injected subcutaneously into animals. Foci of pus appeared in various parts containing for the greater part pure cultures of the streptococcus. Cultures from the blood and kidneys also revealed that streptoccus and albuminuria was often present during life. The streptococci thus showed themselves to be the metastatic forming element while the bacilli of putrefaction (that were injected with the streptococci in the putrid culture) did not become generalized during life. In this way the virulence of the streptococcus could be increased and streptococci which had lost their destructive power could thus regain it. The

local pyogenic properties could also be intensified. Whether this occurs in the human subject is open to question but certainly there is a great resemblance in the conditions. The action of the streptococcus is assisted by the presence of the products of putrefactive micro-organisms. [Perhaps the most interesting part of this work is the further demonstration of the increase in virulence of bacteria by associating them with decomposed material. In 1892 Lesaje and Macargne (*Archiv de Med. Exper.* No. 2, 1892) discovered that *bacillus coli communis* became increased in its virulence when it was associated with diseased organs. The fact is well-known that streptococci are very generally distributed over the mucous membranes and if their septic properties are increased by any pathological change in the membrane on which they live they furnish additional dangers to the animal body. At most care should be taken to thoroughly cleanse all surfaces on which they exist when there is danger of rupture or the development or lodgment of diseased tissue.—Ed].

# TRANSLATIONS.

## THERAPEUTIC HINTS.*

IN CHARGE OF THE TRANSLATOR F. H. PRITCHARD, M. D.

### SCOPOLAMINE HYDROBROMATE.

Dr. L. Illig (*Wiener Medizinische Presse No. 38*, 1893), finds this drug to have a more rapid action, even in weaker solutions, than atropine, while in stronger solutions, it produces a greater dilatation of the pupil. Its duration of action, even in the strongest possible solutions, is much less than that of atropine. In case of idiosyncrasy with atropine it is an excellent substitute, as after long use no disagreeable disturbances nor side-action was observed. It is also of service in all those inflammatory ocular affections where atropine is contra-indicated on account of its increasing intraocular pressure. For diagnostic purposes cocaine is to be preferred.

### PALPITATIONS IN ARTERIOSCLEROTICS.

Dr. Smakovsky (*La Semaine Medicale*, 55, 1893) recommends, in the palpitations of arterio-sclerotic patients from cardiac weakness, the following formula:

℞
Chloral Hydrate .....
Bromide of Sodium, ana .... gms. 4, (ʒj).
Codeine,..... cgms. 10 (grs. jss.)
Water .....
Syrup of Orange Peel ana.... gms. 45, (ʒjss.)

A tablespoonful every two hours until the heart becomes quiet.

In case of necessity one may give injections of morphine, $\frac{1}{10}$ gr. After th attack is once overcome then give small doses of digitalis or strophanthus.

*From the Foreign Journals.

### AN EPILATORY IN SKIN DISEASES.

Dr. Butte (*Wiener Medizinische Presse* No. 38, 1893), speaks highly of iodized collodion as an excellent epilatory in certain skin diseases, as, for example, sycosis, and in the following formula:

℞
Oil of Turpentine..... gms. 1.5 (gtts. xxij).
Alcohol ..... gms. 12 (ʒiij).
Pure Iodine ..... cgms. 75 (gtts. xij).
Collodion ..... gms. 35 (ʒj).
Castor Oil..... 2 (gtts. xxx).

Apply once a day, for three to four days, when, on removal, the hairs will be found to have been extracted and adherent to the collodion.

### CHLORIDE OF GOLD AND SODIUM IN BRIGHT'S DISEASE.

Dr. Dowkontt(*La Semaine Medicale* No. 55, 1893,) knowing that the chloride of gold and sodium was, at the same time, diuretic, diaphoretic and alterative, was led to try it in chronic parenchymatous nephritis where the skin is always dry and the urine diminished. This treatment he has employed for a number of years, with excellent results except in very advanced cases, or those complicated with hydrothorax or hydropericardium of ancient date. He uses the following formula:

℞ Chloride of gold and sodium.... gm. 1 (grs. xv).
Water..... gms. 60 (℥ij).
Six to twelve drops of this solution six times a day.

This is the adult dose. When the affection is complicated by gastro-intestinal disturbances it will be well to commence treatment with doses of two drops, and increase the dose as the digestive functions improve. The use of the drug should be continued until complete suppression of the albuminuria *i. e.*, in some cases, for months. The action of the remedy is slow and may require a month before it becomes manifest. It will be seen that the perspiration will increase with a diminution and final disappearance of albumen from the urine. In the writer's cases this amelioration was so great that the patients were able to resume their businesses and be considered as cured. In some of them no recurrence has been observed. Its curative action being very slow it can not be used in uremic cases, where rather drastic purgatives as calomel and jalap would be indicated. The alarming symptoms being removed the chloride may then be given. He permits his patients to follow a mixed diet in case that it be nourishing, easily digested and contain sufficient vegetables which seem to exercise a favorable influence over the organic changes of these patients.

---

### TREATMENT OF ANTHRAX.

Dr. F. Goilav (*Roumaine Medicale* No. 4, 1893) describes a method of treating anthrax which he has used with success in fourteen cases. After washing the region of the carbuncle with a 4 per cent. solution of boric acid, he opens it with a crucial incision extending a half inch into the surrounding healthy tissue. No anæsthetic is necessary except in very nervous and sensitive persons, where three to four injections of a 1 per cent. solution of cocaine may be used. After opening, it is again washed with the boric acid solution and covered with crystallized boric acid over which is laid a piece of sterilized gauze and a bandage. Under the first dressing, which is allowed to remain on for twenty-four hours, the pains decrease in severity, the temperature falls, the general condition ameliorates and sleep and appetite improve. The next day the dressing is removed, the loose necrotic shreds removed, the carbuncle washed again with the 4 per cent. solution and covered with the crystallized acid. The second dressing remains undisturbed for five to eight days. In twelve of the cases three dressings were sufficient to bring about healing in seven to twenty days. Powdered boric acid is less applicable as it forms a mixture with the pus which hinders recovery. The advantages of this treatment are that it relieves the congestion of the tissues, exposes the pus cavity without opening many blood-vessels, is antiseptic and can be carried out without chloroform. It requires but infrequent change of the dressings, produces rapid healing and may be used in any individual or any portion of the body.

---

### OBSTINATE COUGH OF PREGNANCY.

Dr. Tripet (*La Semaine Medicale* No. 55, 1893), in a case of obstinate cough of pregnancy which had resisted all treatment, tried a treatment similar to that used in the incoercible vomiting of that period. The cervix was found swollen, livid, bathed in yellowish pus and with an extensive ectropion. Under the influence of insufflations of iodoform and applications of iodine the fatiguing cough considerably improved and after six applica- of the galvano-cautery to the cervix it disappeared entirely.

---

### ETHER LOCALLY IN INCARCERATED HERNIA.

Prof. Gussenbauer (*Prager Medicinische Wochenschrift* No. 35, 1893), has employed the local application of ether to the hernial tumor according to Finkelstein, in a series of cases. The patient is placed in the dorsal position, with the pelvis elevated, the knees and thighs flexed and, in men, the scrotal sac supported with a cushion, and, then, every ten minutes to quarter-hour, from one to two table-spoonfuls of sulphuric ether are poured on to the hernial ring and the tumor. This is continued until the tensely distended tumor loses its tension and slightly diminishes, which will occur in three-quarters to three hours. As soon as this is remarked, if it does not reduce itself spontaneously, a few manipulations will suffice to do that which chloroform anæsthesia and strength failed to accomplish, the intestine slips with astonishingly

ease and loud gurgling into the abdominal cavity. The only exception will be those cases where omentum alone is incarcerated. Out of twenty-five cases etherization was successful in twenty. In three spontaneous reduction occurred without taxis and in one the patient reduced it himself. In the other cases it was easily done with slight manipulation as soon as the sensitiveness of the ring and the tension and volume of the tumor were diminished. Most frequently reduction was done in two to three hours, at the earliest in an hour, and twice in five to six hours. The ether is not the only effectual agent for by elevation of the pelvis for some time, with slight taxis, some hernias were reducible, yet the influence of the ether was noticeable. This method if used soon after incarceration will succeed in the majority of cases and is of especial service in country practice. [Hypodermic injection of morphine ($\frac{1}{4}$gr.) and atropine ($\frac{1}{150}$gr.) into the region of the ring is also of service.—Ed.]

---

### IODIDE OF POTASH IN HEADACHE.

In the *Anales Of Del Circulo Medico Argentino*, Tomo XVI, No. 5, 1893, the iodide of potash, in small and frequently repeated doses is recommended as an efficacious remedy in headache. Two grains in an ounce of water every quarter hour will relieve completely, in a short space of time, frontal headache accompanied by sensations of heat and chilliness, languor, general malaise, repugnance of food and nausea. These headaches are from definite or special causes and may be regarded as sympathetic headache with a slight syphilitic element, which is either hereditary or acquired. The iodide of potash administered in this manner, often exercises a marvelous action.

---

### TREATENT OF LEUCORRHŒA.

Dr. Gallois (*Anales Del Circulo Medico Argentino* No. 5, 1893) speaks highly of the following formulæ in the treatment of leucorrhœa:

℞ Sulphate of Copper, ..... 1gm. (grs. xv).
Water, ..... 256 gm. (℥viij).

To be used as in injection in chronic leucorrhœa. At the same time a ferruginous tonic and general baths should be prescribed.

℞ Salicylic Acid.....6 gms. (ʒ jss).
Glycerine.....128 (℥iv).
Water .....1 quart.

Dissolve the salicylic acid in the glycerine, over a fire, and then add the water.

To be used in six injections, one each day, in cases where the leucorrhœa is due to inflammation or irritation in the neighborhood of the uterus or vulva.

---

### PHOSPHORUS IN OSTEOMALACIA.

Dr. Steinberg (*Gyógyászat* No. 36, 1893) recommends phosphorus in the treatment of osteomalacia and in the following formula:

℞ Phosphorus..... 5 cgms. (gr. j).
Cod-liver Oil..... 50 gms. (ʒj ss).

A teaspoonful once a day.

---

### FORMULÆ FOR THE ANTISEPTIC TREATMENT OF BOILS AND CARBUNCLES.

Dr. E. Gourine (*Le Semaine Médicale* No. 56, 1893) has found the following formulæ of value, in the antiseptic management of boils and carbuncles:

℞ Chloroform..... 30 gms. (ʒj).
Essence of Canella..... 10 (ijss) ʒ.
Carbolic Acid..... ½ (gtts.xv-xlv).
Camphorated Oil..... 50 (jss ʒ).

℞ Chloroform .....gms. 30 (ʒj).
Essence of Cloves..... gms. 5-10 (ʒj¼ʒiss).
Beechwood Creasote .....gms. 1-2 (gtts. xv-xxx).
Camphorated Oil.....ʒms. 50 (ʒjss).

℞ Sublimate..... 10-30 cgms. (grs. jss-ivss).
Carbolic acid..... 1-3 gms. (gtts xv-xlv).
Alcohol..... . . 10-30″ (ʒijss-ʒj).
Distiiled Water. ... 90″ (ʒiij).

℞ Salicylate of Mercury..cgms. 10-30 (grs. jss-ivss).
Salicylic Acid.....gms. 1-2 (grs. xv-xxx).
Alcohol .....gms. 10-20 (ʒijss-v).
Distilled Water .....gms. 80 (ʒijss).

℞ Biniodide of Mercury..cgms. 10-30 (grs. jss-v).
Tincture of Iodine ,....gms. 1-2 (gtts. xv-xxx).
Glycerine .....
Destilled Water, ana...gms. 50 (ʒjss).

A compress soaked with one or the other of these solutions is applied to the furuncle or carbuncle, and, at the same time, subcutaneous injection of one of the following injections is made:

℞ Carbolic acid..... 10-20 cgms. (grs. jss-iij)
Sublimate..... 5 mgms. 1 cgm. (1-15; 1-5 gr. )
Sodium Chloride. 7 cgms. (grs. x.)
Distilled water... 10 gms. (ʒi jss.)

℞ Carbolic acid..... 10-20 cgms. (gtts. jss-iij).
Salicylate of Soda.
Biborate of Soda... ana, 1 gm. (grs. xv).
Glycerine..... 2 gms. (gtts. xxx).
Saturated Solution of Chloroform, 8 gms. ʒij).

℞ Iodoform..... 30 50 cgms. (grs. iij viij).
Salol..... ... 5 dgms.-Ug 1 gm. (grs. vijss-xv).
Carbolic acid.. 10 cgms. (grs. jss).
Ether..... 2-4 gms. grs. xxx-ʒj).
Alcohol..... 6-8 gms. (ʒjss-ij).

This treatmeut has given him excellent results and has prevented employing surgical measures.

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

THE MEDICAL CHRONICLE,

(of Manchester, Eng.) for October. Dr. H. C. Dalton, M. A. M. D., contributes a paper on

**Smallpox in its Relation to Vaccination and other Means Designed for its Prevention.**

The paper is based on the critical examination of one thousand recent cases and deals with the three preventives of the disease, vaccination, isolation and healthy environment. Of the thousand cases under consideration 35 were fatal, giving a mortality of 8.5 per cent. As the result of his investigations he believes we have good cause for assuming—

1. That primary vaccination, successfully performed, is an almost absolute preventive of smallpox for a few years, and that in the few instances of smallpox that occur, the attacks are almost invariably mild.

2. The preventive effect wears off to a great extent in a few years. After this time it is not unusual for vaccinated persons to take smallpox, but the severity of the disease is on an average much less than in the unvaccinated.

3. Good vaccination marks, except by affording better evidence of the fact of previous successful vaccination, are only superior to bad marks for a few years. After this time, the important evidence is derived from the actual presence of marks and not from their quality.

4. There is a slight superiority of three marks and over as against two marks and under, but the difference is not very marked, and similarly, with regard to foveated as against unfoveated marks.

5. It is very probable that vaccination marks wear out in course of time. Good marks turn into bad marks and bad marks turn into no marks. Consequently, in the young, persons with no marks have, in all probability, never been vaccinated, but in old people, many of the vaccinated will be in this class.

6. Re-vaccination acts like primary vaccination in that absolute protection is procured for a few years only. After this interval, the re-vaccination will have added nothing to a successful primary.

7. The protective power of vaccination does not reach its height for at least three weeks. If, therefore, exposure to infection takes place less than a week after vaccination, smallpox may occur, though probably in a mild form. Even if, however, vaccination be performed just before the outbreak of smallpox, it is likely to be successful, and in this case will probably modify the disease.

8. Persistently unsuccessful re-vaccination denotes insusceptibility to smallpox, though one or two failures may be due to other causes.

The author also discusses the duty of the state in reference to vaccination and preventive measures, such as isolation. He comes to the following conclusions: There should be one central authority, who shall see after removal, disinfection, vaccination and all other matters appertaining to small-pox, with power to compensate persons who will undergo voluntary quarantine or otherwise indirectly suffer from having come in contact with smallpox. This central authority should do its utmost to persuade persons to be vaccinated or re-vaccinated, and it should make that one condition of receiving any compensation; it should have power to visit casual wards, shelters, etc., isolate suspicious cases, vaccinate and re-vaccinate, if necessary, all who receive relief from the parish, all who are placed in institutions licensed by the State, and all persons employed by the State.

The paper also includes elaborate tables compiled from the records of the London hospital ships

The remaining paper is by Ernest S. Reynolds, M. D., (Lond.), M. R. C. P. and is entitled "Some Remarks on the Diagnosis and Treatment of Neurasthenia."

THE PACIFIC MEDICAL JOURNAL

for October. Dr. Edward VonAdelung, in a paper entitled

**Bowel Paralysis or Septicæmia?**

calls attention to a peculiar set of symptoms which sometimes develops after ovariotomies, and which is sparingly noticed by authors, those referring to this complication using the term "bowel paralysis" or considering if under the head of septicæmia.

The condition referred to is characterized by the development of vomiting, marked tympanites, rapid weak pulse and locked bowels, while the temperature, entirely independent of the pulse, may be high or not. The patient is free from pain, though decidedly collapsed. The vomiting is continuous and before long assumes a grumous character. The pulse runs up in the forties, and there seems to be no parallelism between it and the temperature. The patient is extremely weak and collapsed, but complains of no pain even on pressure over the abdomen. The reason for terming the condition "bowel paralysis" is, that most frequently all efforts to produce a passage of gas or fæces meet with disappointment. And it does not seem wise to use the term "septicæmia," because of the variability of the temperature, and the remarkable fact that as soon as the bowels are moved, which can occasionally be accomplished, all the symptoms immediately abate. If the bowels cannot be moved, the patient dies.

The facts that the post-mortems often disclose healthy abdominal cavities containing no excess of fluid and absolutely no pus, and that the miscrope discovers no characteristic cocci, would seem to exclude septicæmia. Bowel paralysis appears more probable, though its etiology is difficult. The strongest point in favor of this view is the indisputable fact that, if the bowels are moved, all the symptoms immediately and invariably subside. The practical questions bearing on the subject are the etiology and especially the treatment.

All the various means of stimulating peristalsis have been suggested. Martin recommends electricity and massage. Probably these, with the addition of hypodermic doses of strychnine, prove useful. Salines and calomel early in the after-treatment have their warm adherents. Enemata of ox-gall have proven valuable in some cases. But the therapeutics of this complication needs further clinical study before the best line of treatment can be determined.

Dr. Samuel E. Milliken contributes a "Review of the Operative Treatment for the Radical Cure of Inguinal Hernia." (As this paper also appears in *The Buffalo Medical and Surgical Jouraal* for October, it will be noticed under that journal. Ed.)

The other papers in this month's issue are: "Abuse of Digitalis in Cardiac Diseases," by Dr. J. S. Leonhardt; "The Modern Eye," by Dr. W. F. Southward; the report of an "aneurism of the Superior Mesenteric," by Dr. Fred. W. D'Evelyn; and the report of a case in the later months of pregnancy in which there were only "Twenty four Heart Beats a Minute," by Dr. A. E. Baldwin.

---

THE BUFFALO MEDICAL AND SURGICAL JOURNAL

for October. Dr. George F. Cott contributes an article on

**Intubation.**

The author states that he does not always consider the operation one of necessity as regards the saving of life, but principally to relieve obstructive breathing. No doubt many children in whose larynx a tube has been inserted, would recover without it, but the agony caused by the want of air, before the child becomes delirious, must be fearful. Therefore he urges that in all cases of laryngeal stenosis, pseudo-membrane or no pseudo-membrane, if life is threatened, insert a tube, and if the child dies, it will certainly die happy. The tube also serves another purpose. In diphtheria, for instance, when the membrane does not extend to the bronchi, the pressure exerted upon the surface of the tube causes maceration of the pseudo-membrane and its consequent expulsion by coughing, thereby preventing its active absorption.

The cause of the second obstruction, sometimes observed after the child has apparently recovered and after the tube has been removed for three or four days, cannot possibly be due to the formation of false membrane, as that cannot develop so quickly, but seems to be caused by the relaxed tissue, and possibly the vocal cords, having been pressed apart for several days, suddenly collapse, and thus shut off the air.

Occasionally, sudden cessation of respiration occurs after the tube has been introduced, caused by false membrane occluding the opening. In that case a small catheter may be passed through the tube to push the membrane out of the way, and while doing this the child will probably die ; it is better, therefore, to withdraw the tube immediately, as the irritation attendant upon the manipulation usually causes coughing, and the false membrane is expelled often in sufficient quantity to relieve the stenosis.

The tube may be retained any length of time but it is well to remember that enough irritation may be set up to cause erosion, and finally granulations which occlude the tube, when removal becomes necessary, probably the larynx dilated and a larger tube inserted, which will press on the granulations and cause their absorption. In acute cases stenosis from edema or pseudo-membrane the tube is not left in long enough to produce such an effect. The author makes it a rule, if the child's condition permits, to remove the tube on the third or fourth day and reinsert it if necessary.

The present O'Dwyer gag, or any other, has given more trouble than is convenient, constantly slipping, and even breaking, under the enormous pressure exerted by the jaws of the child. In order to run less risk of being bitten, the author has had a ring made to fit upon the index finger, between the second and third joints, the most exposed part; it is broad above and narrow below. The dorsal surface of the finger, being rather thin, is easily penetrated, while the palmar surface being thick, is not affected. Mobility is not lessened by its use, as is the case with other protectors found in the shops.

The author insists on early intubation, not in preference to tracheotomy, but to give the child a very fair chance to recover, if that be possible; for certainly a small proportion die for want of air, and that is always obviated by the tube. The principal objectivesymptom, among others, which always means obstruction somewhere in the air passages above the bronchi, is a very marked recession at the pit of the stomach at every inspiratory effort, and cannot be overlooked.

Intubation is just as efficient in the adult as in the child and the author advises the use of the twelve year O'Dwyer tube in edema or any other obstruction of the larynx in the adult, if no larger tube is at hand. He advises in such case to allow the thread to remain attached to the tube to prevent slipping. He thinks intubation preferable to tracheotomy in such cases, especially when obstruction is not likely to be of long duration ; moreover, no scar is left, as in tracheotomy. Even in chronic stenosis, it seems to be more serviceable than the tracheotomy tube.

Dr. A. B. Judson discusses

**The Treatment of Pott's Disease of the Spine.**

In the treatment, the end in view is to relieve the bone of the duty of supporting weight and concussion; and to prevent the affected joint from motion, believing that the arrest of these two functions, weight bearing and motion, are essential to good treatment. It is not wise to keep the patient recumbent for the long period necessary. And, since the patient must be up, and, to a certain extent, active in locomotion, our best resort, in the author's opinion, is to take what benefit can be had from the application of a lever making pressure from behind forwards in the neighborhood of the posterior projection, and counter-pressure from before backwards at two points, one above, and the other below the level of the seat of the disease. In a limited sense, this application relieves the diseased joints from the weight of the body while the patient is up and about; because antero-posterior pressure, thus applied, transfers a part of the weight and concussion incident to standing and walking, from the diseased bodies of the vertebræ to the processes, which remain sound.

The apparatus needed is essentially simple, consisting of two parallel uprights, united below by a pelvic band, and diverging at their upper ends at the base of the neck, and curving over the tops of the shoulders. Pressure from behind forward is made by two pads attached to the uprights at the level of the projection, and applied a short distance from the median line on each side. Counter-pressure from before backwards is made below by a strap passing from one end of the pelvic band to the other in front of the pelvis, and above by straps, one on each side, passing from the upper end of the upright through the axilla, to be buckled to the upright. The most important feature of a brace constructed to carry out these views is the use of mild steel for all the metal parts. The use of this material puts in the hand of the surgeon the power to modify the degree and direction of pressure to the changing shape, and to meet the increasing tolerance of the skin to pressure. The reaction of the skin should receive special and constant attention, and gentle and gradually increasing pressure should be made till the limit of comfortable tolerance is reached.

---

Dr. Samuel E. Milliken contributes a

**Review of the Operative Treatment for the Radical cure of Inguinal Hernia.**

After having looked up more than three hundred cases of recurrent hernia after various methods, which came under the author's care at the "Hospital for Ruptured and Crippled," he is convinced that the percentage is far greater than the operators are led to suppose by the immediate apparent good results. It is his opinion that too much is expected from the radical operation, owing to the fact that, with all of nature's devices, she has failed to let the structures of the spermatic cord make their exit from the abdominal wall without leaving each subject liable to hernia, no age being exempt. So long as it is not deemed advisable to sacrifice the testicle, the best that we can hope for is to imitate nature and re-establish the obliquity of the canal. This is best done, in the author's opinion, by the method of Bassini, which is as follows. First, the aponeurosis of the external oblique muscle is divided over the cord structures, until the internal ring is well exposed; the flaps are separated from their underlying structures, until the conjoined tendon on the upper and the shelving process of Poupart's ligament on the lower are brought into view. The cord structures and the hernial sac are next lifted out of their bed *en masse*, after which the sac is isolated, opened and tied off at the highest point. Secondly, with the cord held out of the operation field by a blunt hook or the finger of an assistant, the conjoined tendon, on the upper is sutured to the shelving process of Poupart's ligament on the lower, by means of the kangaroo tendon or chromatized cat gut. The author prefers the kangaroo tendon, as the time for absorption is longer, and the sutures are stronger for their size. From four to six interrupted sutures are sufficient to make a firm posterior wall for the cord structures, care being taken not to constrict them at the internal ring.

Thirdly, the obliquity is re-established by bringing together the flaps of the external oblique by a continuous suture of the same material. The skin wound is closed with interrupted catgut sutures without drainage.

Of something over the thirty cases operated on by the author after this method, he has had three recurrences. In each suppuration occurred, and the hernia made its appearance during the first six months. In regard to treatment tho author comes to the following conclusions:

1. Reconstruction is the best method.
2. No drainage should be employed.
3. The use of trusses should be prohibited afterwards.
4. While a certain percentage will recur, the operation is justifiable between four and forty years of age, unless some physical disability contraindicates the same.
5. Where omental or intestinal adhesions exist, and the use of a truss is unsatisfactory, the operation should always be attempted, as the danger from strangulation is greater than that from the employment of an anesthetic.
6. It is advisable to attempt a radical cure in all cases operated upon for strangulation, unless the gut be gangrenous or the patient's vitality too low.
7. Where undescended testes exist, it will usually be found to be complicated by hernia, and at the time the organ is anchored to the scrotum, the inguinal canal should be reconstructed.

The remaining papers in this issue are "School Life and Physical Development," by Dr. Louis A. Weigel; and "Cysts of the Nasal Passages" by Dr. W. S. Renner.

THE AMERICAN JOURNAL OF OPHTHALMOLOGY

for July opens with an article by Dr. A. Schapringer of New York, on

**Iritis as a Symptom of Bright's Disease.**

Illustrated by a case to which he was called on October 28th, 1890. Dr. Schapringer thus describes it: "I found the patient a man about thirty-five years old, sitting up in a darkened room, his posture and the expression of his face revealing intense photophobia. Before I proceeded to examine his eyes he told me that he had been under treatment for the last three weeks by Dr. Louis Conrad for an affection of his kidneys and that when his eyes began to trouble him, Dr. Conrad had advised that I be consulted.

"The lids of both eyes which were kept closed by the patient were not swollen. He complained of intense pain in his right eyeball, which was extremely sensitive to touch and could not bear the slightest pressure exerted upon it. There was well marked œdema of the conjunctiva bulbi, but not associated with any change of the normal white appearance of this membrane. The cornea was clear, but the aqueous humor was slightly turbid. No precipitate could be made out on the posterior wall of the cornea. The iris looked discolored and dull and the pupil was contracted, but regular in outline. An ophthalmoscopic examination or tests as to the acuity of vision could not be made, beyond the fact that a fog seemed to cover the field of vision of that eye." Dr. Conrad stated there was no history of syphilis in the case but that the patient had come to his office three weeks before, complaining of headache and nausea and looking badly. The Doctor immediately suspected Bright's disease, which suspicion was confirmed by an examination of the urine. "As a local treatment of the eye I prescribed the instillation of a solution of atropia sulphate, gr. i. to ℥ss every two hours. Whilst the patient on the next day felt considerable relief in his right eye, his left eye now began to trouble him in the same way as the right. Under the same treatment both eyes improved and were well in about six days." * * * "The patient's death occurred on December 6, 1890, about five weeks after the first onset of the eye trouble. I learned that two weeks before the patient's demise the sheaths of the extensor tendons of the right hand became inflamed. A few days before the end this inflammation subsided to be replaced by an attack of pericarditis to which the patient succumbed in a uræmic condition. No autopsy was made."

Dr. Schapringer was led to associate the iritis with the kidney disease from a recollection of Leber's case published a few years ago.

The remainder of this number is occupied by a translation from Dr. H. Cohn's work on "Hygiene of the Eyes." It deals especially with that portion devoted to the consideration of

**The occurrence of Myopia among School Children.**

The details of this elaborate and valuable paper are too lengthy for us to reprint, but the following facts and deductions will be interesting to our readers:

"Myopia is a very widely spread disease. Among 40,000 patients that came into my clinic, 6, 707 were short sighted, that is 16.8 per cent. Mooren observed among 108,416 patients 8,452, 7.8 per cent. suffering from myopia.

"A far better insight into the extent of myopia than reports from eye clinics, is given by researches among school children, and we possess in this regard materials which do not exist in such completeness in the case of any other disease."

"I undertook, in 1865–6 the examination of 10,060 school children in schools of all grades. I found 83 per cent. of emmetropia, 13 per cent of errors of refraction (of this 10 per cent. myopia) and 4 per cent. of other eye diseases. The frequency of myopia is shown in the following table: I noticed in

| | Per cent. M. |
|---|---|
| 5 Village Schools | 1.4 |
| 20 Elementary Schools | 6.7 |
| 2 Higher Girl's Schools | 7.7 |
| 2 Intermediate Schools | 10.3 |
| 2 Realschulen | 19.7 |
| 2 Gymnasiums | 26.2 |

Therefore among 10,060 children 1,004 M. 9.9 per cent.

From this follows: 1. *That in the village schools only a few appeared short-sighted; that on the contrary, in the city scholols the number of the short-sighted continualy increases from the lowest to the hiyhest school;* that, therefore, the number of the short-sighted stands in direct proportion to the longer strain to which the eyes have been subjected.

2. *That the number of the short-sighted from class to class in all schools increased.*

Also, with increasing age the degree of myopia increases; although the higher degrees of myopia occur more frequently in the first four school years than in the seventh to tenth year of age."

*The average degree of short-sighted pupils is constantly increasing from the village schools to the gymnasium.*

Dr. Cohn agrees with Erismann in the conjecture that "hyperopia is the normal condition of refraction in the youthful eye, and that only the smaller portion of the cases remain far-sighted. The majority become short-sighted after they have passed through the state of normal sight."

After furnishing a large number of statistics he says "From all the figures given above it only follows with certainty *that in the whole civilized world, in all nations, the number of the short-sighted increases with the demands which their school work makes, and from class to class*" and "We declare ourselves of the opinion that *in the schools everything should be so arranged that it will not cause injury to the eyes.*"

# PERISCOPE.

IN CHARGE OF WILLIAM H. BRICKER, M. D., B. SC.

## MEDICINE

### Eye-Paralyses.

The *Amer. Jour. Ophthalmology* contains a very comprehensive article on the paralyses of occular muscles. The following is a summary:

1. All cases of lateral conjugate paralysis are of central origin.

2. When the paralysis is on the same side as other paralysis, the lesion is on the opposite side of the brain. Such paralyses as a rule are transitory, and follow almost any sudden lesion, and often show themseves as a prevailing position of the eye, and not as a true paralysis, or even paresis.

3. When the paralysis is crossed with the paralyses below, the lesion is in the pons-medulla region.

The above three conclusions are equally true of spasms

4. A gradual development of conjugate paralysis clearly points to the region of the sixth nucleus of the same side as affected.

5. Paralysis of up or down motions, or both motions, indicate disease in the region of the corpora quadrigemina, at the point of exit.

6. Reasoning from anology, paralysis of convergence points to disease in the central gray below the aqueduct, but as yet autopsies are lacking.

7. Picked paralysis of parts of a third nerve strongly suggests central disease, but is not proof of it.

8. A majority of cases of eye-paralysis occur in the syphilitic.

9. A paralysis which changes rapidly, quickly showing fatigue, is probably central in origin.

10. Transitory paralysis in the syphilitic is strongly suggestive of future tabes.

11. An eye paralysis, however simple it may seem, is always a just cause for suspicion of trouble to come, and demands a prompt and thorough examination of the patient.

12. There is no evidence that there is any form of connection between the sixth nucleus and the third except in the cerebrum.

### Diagnosis of Inebriety from Apoplexy.

Dr. Mills, in a recent clinical lecture on the case of a man picked up in the street unconscious, remarked as follows:

"This man has no external evidences of fracture; but sometimes without fracture or with concealed fracture, a sudden fall or blow on the head will produce an extra-dural or sub-dural hemorrhage. Such patients are usually unconscious at first, and often regain or partially regain their senses, and again lapse into unconsciousness. One dilated pupil, convulsions, and some hemiparesis, are among the prominent symptoms of such a lesion. The signs and symptoms present do not point clearly to this lesion.

"Other diagnoses to be considered are those of drunkenness, opium poisoning, epilepsy, uremia, and embolism or cerebral hemorrhages, perhaps still others, but these are the most important.

"Profound alcoholic intoxication can be excluded, as this patient is evidently absolutely unconscious, and suffering from profound paralysis, more marked on one side than on the other. In dead drunkenness, while consciousness may appear to be lost, the condition is rather one of extreme stupor or stupidity, and the patient by strong excitants can usually be made to respond in some way, although he may immediately sink again into his stuporous state. The smell of liquor on the breath may help, but this cannot be relied upon, as a patient insensible from any cause may have been drinking. Both sides of the body are equally affected in extreme alcoholic intoxication.

"Several facts will easily exclude opium poisoning, such as the sudden onset, the absence of pinpoint pupils which will not dilate, and the peculiarities of the state of insensibility. As the man was seen at the time of and immediately after his attack, and for other reasons, the post paroxysmal sopor of epilepsy can be dismissed.—*Jour of Inebriety.*

### Dawson (Rankin) on Sbocrrhio Eczema.

Under this title Unna includes:

1. Seborrhœa capitis, pityriasis capitis, scurvy, or dandruff.

2. Seborrhœa proper, where greasy crusts are found on the scalp.

3. Lichen circinatus of Willan, or seborrhœa corporis of Duhring.

4. A number of chronic exezmatous eruption affecting the back of the ears and sometimes the folds of the joints, and frequently associated with a scurfy condition of the head.

5. Cases occupying apparently an intermediate position between psoriasis and eczema, well defined and scaly on some parts, less well defined and moist on others.

The writer closes his discussion as follows:

We are then, we believe, justified in concluding—

1. That Unna's "seborrhæic eczema" cannot be regarded as a separate or distinct disease, but rather as an interesting group of affections.

2. That patient in whom the sebaceous system is exceptionally active or exceptionally developed are especially liable to these affections.

3. That eczematous, psoriasiform, syphilitic, and, indeed, almost all eruptions are

likely to be modified in character and appearance in the case of these patients.

4. That the skin of such patients affords an exceptionally favorable soil for the growth of many kinds of parasites, which in their turn tend to modify the character of pre-existing eruptions, or to induce further inflammation.

5. That the treatment of these affections should, in the first instance at least, be directed against this parasitic element when present.

Unna's theory that the seborrhœic affections are dependent largely or chiefly on the sweat glands must, we believe, be regarded as, to a large extent, purely hypothetical and as yet unproved.—*Montreal Med. Jour.*

## THERAPEUTICS.

### The use of Cocaine.

1. Amount of cocaine used must be in proportion to extent of surface it is desired to anæsthetize. In no case should the quantity exceed one grain and three-quarters.

2. Cocaine should never be used in cases of heart disease, pulmonary disease, or in persons of highly nervous temperament.

3. In injecting cocaine, the intradermic method is preferable to hypodermic. By injecting into, not under mucous membrane or skin, the risk of entering a blood vessel is avoided.

4. During injection the patient should always be in a recumbent position ; in operations upon the nose and throat, the head should not be raised until anesthesia is complete.

5. It is of great importance that cocaine should be pure, since its combinations with certain other alkalies result in poisonous compounds.—*Brooklyn Med. Jour.*

### The action of Pilocarpine on Bodily Temperature.

In a series of experiments conducted by Professor Reichert on this drug the Doctor states that the results of his observations justify the following conclusions :

(1) Pilocarpine first increases and then decreases bodily temperature.

(2) Heat production and heat dissipation are first increased and then diminished. Heat production is the process primarily affected, the alterations in heat dissipation following and being dependent upon the effects upon heat production, excepting after very large doses, when heat dissipation may be depressed even more than heat production during the stage of lessened heat production.

(3) The alterations in temperature are dependent essentially upon the actions on heat production, but may be affected by sweating, and after very large doses by alterations in heat dissipation.

The primary increase of temperature is due primarily to an increase of heat production, but after very large doses this increase may be exaggerated and continued by a diminution of heat dissipation which is greater than the depression of heat production.

The decrease of bodily temperature is due to a diminution of heat production, but may, in part, be due to sweating.

(4) The actions on the process of heat production are so much more potent in their effects on temperature than those on the sweat glands, that it is doubtful if the latter ever plays an important part in the temperature alterations.

(5) Bodily temperature may be increased during the stage of diminished heat production, owing to the greater depression of heat dissipation.

(6) The amount of increase and decrease of temperature and the duration of each of these periods are essentially in direct relation to the dose.—*Univ. Med. Mag.*

### The Admisistration of Anesthetics.

The following deductions (*Lancet*, No. 3642, p. 1498) have been arrived at by the Commission appointed by the *Lancet* to investigate from a clinical standpoint the subject of the administration of chloroform and other anesthetics: The death-rate under anesthetics has heretofore been unduly high, and may be lowered by improved methods and greater care. Ether is the safest anesthetic in temperate climes for general surgery, when properly given from an inhaler permitting graduation of the strength of the vapor. Nitrous oxide gas should be employed for minor surgery. Chloroform is a comparatively safe body when given by a carefully trained person, but is not in any case wholly devoid of risk. No age or nation is free from danger under anesthetics. The perils of anesthesia, however slight, demand that the undivided attention of a duly qualified and trained medical man should be given to the administration of the anesthetic.

### Rules for Passing the Sound.

1. Place the patient in the reclining posture, and make the flexures described—at least flex the thighs.

2. Lubricate the urethra by injecting alboline, or some refined oil; if the oil is not cocainized and it is desirable to use cocaine, it should be first applied.

3. Make the urethra tense by traction.

4. Avoid force; go slow; be patient.

5. Guide the instrument if obstructed in the deep urethra, by the finger introduced into the rectum.

6. All instruments are to be made surgically clean and perfectly smooth.—*Med. Brief.*

### Gibby (F. H.) on the Surgery of Childhood.

The principal danger is from hemorrhage, as children bear poorly the loss of blood. But removed from the operating table alive, they are the best subjects. Inflammation rarely passes the degree necessary for repair, while pyæmia is less to be feared. Chloroform is the anæsthetic and properly given is perfectly safe.—*Mass. Med. Jour.*

## ORIGINAL ARTICLES.

# CONTRIBUTION TO THE STUDY OF YELLOW FEVER FROM A MEDICO-GEOGRAPHICAL AND PROPHYLACTIC POINT OF VIEW IN THE MEXICAN REPUBLIC.*

EDUARDO LICEAGE, M. D., Mexico.†

At its meeting held last year in Mexico City, the American Association of Public Health appointed an International Committee "On the origin, causes and development of yellow fever, and the proper means to wipe it out at its birth."

I had the honor to be named as one of the members of this Committee, and I have since received a letter from Dr. Formento, its President, in which he uses the words: "We hope to be able to present at the next meeting a partial report, at least, on this important international sanitary question, and in order to facilitate the work of the Committee, each individual member of the same is urgently requested to give full expression to his views on the subject, and indicate sanitary measures and local reforms or improvements in the reputed habitants of yellow fever, as he considers most effective to bring about the greatly desired object, namely, the stamping out of the scourge in its very cradle."

I have copied the exact text of the words used by the President of the Committee in order to show the manner in which we ought to enter upon the consideration of this important problem, with a view to a satisfactory solution.

If each one of the members of the Committee undertakes to treat the whole of the question he will necessarily have to repeat a great deal that has been previously said by other physicians that have discussed the subject; but if I only undertake the study of a limited portion of the problem, I may, perhaps, be able to throw some light on the subject, and with that object in view, I now propose to present to the Association a brief study containing all the information of a positive character which has been acquired in the Mexican Republic, with respect to the following points:

1. Places which we may consider as *centres* of yellow fever, on the coast of the Gulf of Mexico.

2. Localities in which the yellow fever does not originate, but which present favorable conditions for its development once it has been imported from any other place.

3. Epidemics of yellow fever which have invaded different localities of the Coast, specifying the causes which have given rise to the same, based on exact data in our possession.

4. Immunity which is enjoyed by individuals born in places where the fever prevails with an endemic character, and

* Read before the International Congress of Public Health, October, 1893.

†Vice-President of the American Public Health Association, President of the Supreme Board of Health of Mexico, Professor of Surgical Therapeutics in the School of Medicine, Director of the Maternity and Infant Hospital.

the manner in which we are to understand this immunity.

5. Inoculations of Dr. Carmona to obtain this immunity.

6. Measure of sanitary police which I consider indispensable to prevent the importation of yellow fever in those localities which favor its propagation and development.

The Mexican Republic is situated to the south of the United States of America and extends between the parallels of 14 and 32 degrees of north latitude, with width covering 30 degrees of longitude, and an area of 2,000,000 of square kilometres. On the west it is washed along the whole of its coast by the Pacific Ocean, which takes the name of the Sea Cortez or Gulf of California in that part which separates the Peninsula of California from the mainland of the continent, and on the east it is washed by the Gulf of Mexico and the Caribbean Sea.

On the Pacific Ocean the Republic of Mexico has 6,250 kilometres of coast, and 2,580 on the Gulf of Mexico.* This enormous extent of coast is considered by Europeans, and even by Americans, to be extremely unhealthy, they having an erroneous impression that on those coasts yellow fever originates and develops in a *spontaneous* manner. I desire to correct this error, by informing the Association that in the entire Pacific coast and in the 3,000 kilometres of coast on the Peninsula of Yucatan, yellow fever *has never appeared in a spontaneous manner*. Neither has it appeared in the greater part of the coast that forms the Gulf of Mexico.

I will now indicate the localities which were considered as centers of infection, for the reason that yellow fever prevails in them in an endemic form.

The City of Vera Cruz, in the port of the same name, occupies to-day the same position that it has had since the year 1599.

The investigations which have been undertaken by physicians and historians have never been able clearly to determine whether the yellow fever originated in Vera Cruz, or was imported from other parts. Many authors are inclined to adopt the latter opinion, and especially Dr. Charles Heinemann, a distinguished German physician, who for many years practiced his profession in that port and from whose interesting works I have taken many of the data for this paper.* However this may be, the fact is that Vera Cruz for more than two centuries has been the most important hotbed of yellow fever in the whole coast. From this point the troops started in 1843, who introduced the disease for the first time in the port of Tampico. The epidemics which ravaged the same port in the years 1847–8, and 1863–4, owe their origin to the same circumstances. In the same way, the disease was carried to Tuxpam in the year 1863,and to Jicaltepec in the years 1861 and 1868. In Vera Cruz the greater part of the epidemics take place in the summer time between March and October, but on some occasions, as in the years 1867–8 and 1877–8, the epidemics raged through the winter.

According to Dr. Heinemann, the port of Alvarado, situated 18 leagues to the southeast of Vera Cruz and near the mouth of the River Papaloapam, is another center of the disease.

Tlacotalpam is a city situated on the left bank of the same river, and at a distance of twenty-five miles from Alvarado. It is also considered by the physician I have mentioned, as a cradle of yellow fever, whilst others† are of the contrary opinion.

Laguna is the principal town on the Island of Camen, and derives its importance from the exportation of dye woods. This is another permanent centre of the disease, which causes numerous victims every year among the foreign sailors.‡

Campeche is the capital of the State of the same name in the Peninsula of Yucatan, and is another source of yellow fever at those times when Federal troops are stationed there, proceeding from the more elevated parts of the country or from abroad. This happened in the year 1865, when two companies of Austrian troops lost the greater part of their numbers through yellow fever. Dr. Patrico Trueba, a distinguished physician who has resided in Campeche for the last 25 years, is also of the opinion that the crowding together of persons who have

† Drs. Gregorio Mendizabal and Diodoro Contreras.

‡ Op. cit., Page 247.

not gone through the disease, favors the development of yellow fever.

The City of Merida, capital of the State of Yucatan, which covers the northern part of the Peninsula of the same name, as well as the districts comprised within that State under the name of Unucma, Progreso, Temax, Tizimin and Valladolid, are considered as centers of yellow fever by Dr. Jose Palomequem, a distinguished physician of Merida, and who declares that the disease in that place finds its greatest development amongst the foreigners who have not already had it, the natives of the elevated table-lands in the center of the Republic, and the Indians from the other towns of the same State. Mr. Zayas Enriquez expresses the same opinion.*

To the districts of the States of Yucutan which I have above mentioned, Dr.† Domingo Orvananos in his recent work adds the district of Motul and Mazcanu as being centres of yellow fever.

The preceding lines will have demonstrated that in the Gulf of Mexico and out of a length of 2,580 kilometres of coast, only that small part belonging to the Canton of Vera Cruz, to the District of Frontera, to Campeche and the northern coast of the Peninsula of Yucatan, can be considered as *centres* of development for yellow fever, as they are in constant communication by sea with each other and with the Island of Cuba. It is to be noted that these last mentioned localities are only separated from the Island of Cuba by a narrow strait, and that it is natural to suppose that the disease was originally imported from that Island.

In contrast to the narrow limits of the centres of infection, we can present the enormous coast line of the Gulf and of the Pacific, where the germs of yellow fever find a fertile soil for their development only when they are transported from those places in which the disease prevails in an endemic form. With the object of rendering my study of the subject more precise and of basing it on exact data, I will now proceed to examine the different points on the Gulf and Pacific coasts from this point of view, taking the greater part of my data from the works which I have already mentioned.

The Port of Metamoros is situated opposite to Brownsville on the United States frontier, and has suffered from epidemics of yellow fever in the years 1858, 1864 and 1867.‡

Altamira went through its first epidemic of black vomit in the month of October, 1821, shortly after the arrival in that port of a vessel from Havana. More than fifteen hundred persons, both native and foreign, succumbed during the ravages of the epidemic.

Tampico, on the left bank of the river Panuco, was visited, as I have previously mentioned, by its first epidemic of yellow fever in the year 1843, twenty years after its foundation. ‖

Tuxpam, on the left bank of the river of the same name, was visited by an epidemic in the year 1838, which was not repeated until the year 1863,and was then imported by vessels arriving from Vera Cruz. It attacked the natives of the locality, the Mexicans newly arrived from the table land and foreign sailors, and it afterwards spread to the villages of Jico and Huauchinango.

Papantla and Misantla were visited by an epidemic of yellow fever of the most deadly character, which was imported by the troops passing through those districts during the revolution of 1876.

Nautla was visited by the epidemic in 1859, and Jicaltepec in the years 1861 and 1868.

Trusting to the information given by Dr. Heinemann, in whose judgment I have the greatest confidence, I give a list of the following towns in which the yellow fever has never appeared within the memory of men: §

Santecomapan, La Barilla, Coatzacoalcos, Santa Ana, Cupilguillo, Dos Bocas, Chiltepec, San Pedro y San Pablo, Barra del Rio Palizada and Champoton. According to many other numerous and reliable reports that I have received, the foreign sailors in those parts have hitherto escaped the disease, in spite of the hard work they have to perform under a burning sun, receiving and stowing the goods with which the ships are loaded.

Although the above mentioned author

‡ Heinemann. Op. cit.
‖ Heinemann. Op. cit.
§ Heinemann. Op. cit.

says that Coatzacoalcos and Minatitlan have not suffered from yellow fever, they were nevertheless invaded by the epidemic in September of last year, the disease being communicated by persons who had arrived from Vera Cruz in the steamer May.*

Frontera has from time to time been visited by mild epidemics, which have attacked both natives and foreigners.

San Juan Bautista de Tabasco had never been visited by yellow fever until the year 1877, when it was imported by the troops under the command of General Enriquez, coming from Campeche and touching in Frontera.

The disease attacked the inhabitants of this town without distinction of race, and afterwards spread to Micaltepec, Huimanguillo, San Antonio, Cardenas, Nacayuca, Jalpa, Pichucalco. Doctor Castanares, who has lived in that locality, believes that the Mexicans, who are natives of the cold country are the first to be attacked by the epidemic, whilst it respects the natives of the State of Tabasco.

I have already mentioned that the epidemic at times spreads from the ports to some of the towns situated within a certain distance of the coast. I now propose to treat, although lightly, of the spread of the disease along the lines of railroads which run from Vera Cruz to Mexico and Vera Cruz to Japan. During the construction of the first mentioned line and as the works advanced, the disease presented itself at all the stations excepting Tejeria, although it is only situated at a distance of fifteen kilometres from Vera Cruz. This station preserves its immunity to this day, whilst in LaSoledad, El Camaron, Paso del Macho and Atoyac a few cases of yellow fever are observed almost every year. But the city situated on this road in which the epidemic presented itself on several occasions, and where it has carried off the largest number of victims, is Cordoba. Situated at a distance of 105 kilometres from Vera Cruz and at an altitude of 827 metres above the sea-level, it has undergone epidemics imported from that port, in the years 1866–7, 1876–7, 1880–1 and 1892–3.† In the year 1876, more than two thousand persons perished in the epidemic which spread to many of the neighboring towns and villages.

Following the ways of communication by the road from Vera Cruz to Jalapa, the epidemic was carried to the towns of San Juan and Paso de Ovejas, but never reached Jalapa, which is almost at the same distance from Vera Cruz as Cordoba, but at an elevation of 1,320 metres above the sea-level.

The highest point in which the yellow fever has, up to the present date, been found susceptible of development, is the village of Las Animas, situated between Cordoba and Orizaba, at an elevation of 1,008 metres above the sea-level.

The extensive coast of the Pacific had always enjoyed an immunity from this epidemic, with the exception of short stretches belonging to the States of Michoacan, Oaxaca and Chiapas, which on two distinct occasions had been visited by yellow fever.

In the localities which I am about to mention, all memory had disappeared of an epidemic of this class, if they ever had known such a thing, so that when it presented itself in Mazatlan, the local physicians did not recognize it, believing that it was not a disease special to that climate. Nevertheless, in August, 1883, the Pacific Mail Steamer, "San Juan," arrived with sick people on board who had imported the yellow fever in Mazatlan. The epidemic spread with such rapidity that within five days 3,000 persons were attacked with the disease. From Mazatlan it extended to Guaymas, San Blas, Acapulco, Manzanille and other places. Amongst these latter I would especially mention Culiacan and Hermosillo, on account of the distance at which they are situated from the coast. The epidemic ceased in the month of October in the same year, and has never been repeated. From the preceding remarks, it will be seen that the immense coast of the Republic, washed by the two oceans, is always liable to be invaded by epidemics of yellow fever when it is imported. Matamoras was visited by epidemics in 1858, 1863 and 1867.

As we have already seen, the epidemic appeared in Altamira during the year 1821, after the arrival of a vessel from Havana.

The first epidemic was carried to

* Report by Don Ignacio Garfias, Inspecting Engineer of the National Railway of Tehuantepec.

† Data furnished by Dr. Gregorio Mendizabal of Orizaba.

Tampica in the year 1843, by troops from Vera Cruz.

To the same circumstance, we attribute the great ravages committed amongst the American troops in 1847–8, who garrisoned that town during the war.

The epidemic was also imported into Tampico during the years 1863–4, by two battalions of the French army. The great epidemic that ravaged Tampico in September, 1878, was imported from New Orleans with a cargo of grain, and acquired its development because it fell on favorable ground, the cyclone which had previously devasted the coast having caused inundations in the neighborhood of the port.

In June of the following year, a large shipment of damaged cotton goods was received in this port, which had been submerged in the sea. These goods were hung up to dry in the rooms occupied by some employes of one of the stores, and this circumstance gave rise to the commencement of an epidemic which lasted until the month of December.

I must here state, that from that date no new epidemic has appeared in Tampico, although isolated cases have been observed in persons who carried the disease with them from Vera Cruz.

Tuxpam was visited by an epidemic in the year 1838.* Dr. Ordozgoiti does not state how the epidemic developed itself, but he clearly declares that the epidemic of 1863, was imported from ships arriving from Vera Cruz. As I have always said, the mulateers carried the disease as far as Jico and Huauchinango. Troops arriving at Tuxam from Vera Cruz introduced the epidemic in the years 1877 and 1878.

Papantla: A detachment of troops passing through this town in the year 1876, brought an epidemic of yellow fever with them which developed the most deadly characteristics.

Nautla: An epidemic took place here in the year 1859.

Jicaltepec: An epidemic appeared in this town in the year 1861, which was limited to the right bank of the River Nautla.† It was also visited by an epidemic in the year 1868.

Coatzacoalcos: The yellow fever was carried to this port in the month of September, 1892, by some sick men on board of the steamer "May" from Vera Cruz.

Minatitlan: The disease was carried to this port at the same time and under the same circumstances as the last one mentioned.

Frontera: From time to time mild epidemics are observed in this town, the disease affecting both foreigners and natives alike.‡

San Juan Bautista: As I have already stated, this port is situated at a long distance from the coast and on the right bank of the River Grijalva. An epidemic raged there in the year 1877, having been imported by Mexican troops which had touched at Frontera on their way from Campeche. From San Juan Bautista the epidemic spread to Micaltepec, Huimanguillo, San Antonio Cardenas, Nacayua, Jalpa and Pichucalco.

Don Francisco Arguelles, who is quoted by Dr. Heinemann, says that the first cases of yellow fever which appeared in Pichucalo, originated in the house of a Spaniard named Bustamante, who had just received a shipment of goods from San Juan Bautista. "These goods were transported up the river in canoes, to a point distant one league from Pichucalco, where they were unloaded and carried to the town by mules. Mr. Arguelles knows nothing of the fate of the canoemen, but he asserts *that all the muleteers* took the disease, A few days after the arrival of the goods all the people living in Mr. Bustamante's house fell sick, and fourteen of them died. From this house the contagion was propagated throughout the whole town, making numerous victims in all classes amongst the residents ; but it was remarked that the Indians who came from the cold country (San Cristobal, Chiapas) succumbed to the disease with *greater facility* than those from the hot country, After a few days the merchandise forming this unfortunate shipment was carried on the backs of Indians to San Cristobal, but on the road itself the porters were attacke by the disease one after the other. The epidemic did not reach San Cristobal, which is five leagues journey from Pichucalo, and its force was greatly diminished by the month of August, although it still continued on a smaller scale till the begin-

* Heinemann.—op. cit.

† Heinemann.—Op. cit.

‡ Mr. Barnard, cited by Dr. Heinemann.

ning of December, when it finally disappeared."

Dr. Castanares, who has practiced his profession for 23 years in Tabasca, says that the epidemics only appear in that State when there occurs a great crowding of people under unhealthy conditions, as for instance, in a military encampment. Dr. Castanares believes that the epidemic attacks with greater facility the natives of the neighboring State of Chiapas. According to Dr. Orvananos* epidemics of yellow fever have visited the State of Yucutan in the years 1855, 1857, 1881–2 and 1883, and have also appeared in the State of Vera Cruz in the years 1863, 1872, 1873, 1875, 1878, and 1879, and in Campeche in the year 1865. The author does not give any details as to the manner in which the epidemics deveioped themselves.

Dr. Orvananos speaks of epidemics having appeared in the State of Michoacan, during the years 1813, 1814 and 1860, but I believe that this can only have taken place along a short stretch of coast, as I can find no record of these epidemics. The same remark applies to the State of Oaxaca during the years 1850 and 1857. In the work of this author to which I refer, he simply says, as I have above shown, that in the States of Jalisco and Sinaloa an epidemic appeared in the year 1882, but this assertion is plainly contradicted by Dr. Praslow,† who says :

"The yellow fever was imported by the American steamers, as I will prove further on, for this disease was never previously seen on the coast of Sinaloa, and Sonora, a fact than can be clearly proved by the books which from the time of the Jesuits have been written, and which speak of other diseases, but not of yellow fever."

The epidemic which spread during the year 1883, along the entire coast of the Pacific, is of the greatest interest in view of the question we are now studying. If any previous epidemics had ever appeared, the memory of them was so completely lost that when the first cases of yellow fever presented themselves in the port of Mazatlan, the physicians did not recognize them, founding their doubts on the fact that this disease had never been seen on the west coast of Mexico. Another great point of interest presented by this special epidemic, is found by following up the way in which the disease was introduced, that is to say, by sea. Dr. Praslow‡ maintains that the yellow fever may have been imported from the year 1882 by the steamers of the Pacific Mail which brought yellow fever patients from Panama, who did not land. He proves this assertion by letters from persons who had traveled in the steamer "Colima," on board of which the captain and six stewards fell sick.

The same did not happen in August, 1883. In that month the steamer, "San Juan" belonging to the same company, reached Mazatlan with 33 sick people on board coming from Panama. Some of them landed, and the consequent epidemic spread with such force, that as I have before said, more than 3,000 people were attacked in the port within the first five days, whilst 22 died in only one day. The epidemic rapidly extended itself to other ports on the coast, and visited the ports of La Paz, Guaymas, Altata, San Blas, Manzanillo, Santiago, Acaponeta, Acapulco, Puerto Angel, Salina Cruz, Tonala, Soconusco, Tapachula and San Benito, and in the interior of Hermosillo and Culiacan.‖ A very important fact to be borne in mind, is that in all the territory included between the Yaqui and Mayo rivers which are inhabited by Yaqui Indians under the command of the valiant chief, Cajeme, the epidemic did not put in an appearance. This was due to the energetic attitude assumed by the chief of the tribe, who prohibited all communication with the outside world, either by sea or land, under penalty of death. This fact has the force of an experimental demonstration and clearly shows the sovereign efficacy of isolation as a precaution against the transmissible infectious diseases.

### IMMUNITY.

It is a universally accepted fact, that an individual who has once suffered an attack of yellow fever, is exempt from any more, but exceptions can be found to this rule, the same as in the cases of typhus, typhoid fever and scarlatina, but

* Op. cit.

† Apuntes sobre la fiebre amarilla en la epidemia que reino en Culiaca en Agosto de 1884.—Culiacan. —1884

‡ Op. cit.

‖ Documents of the Supreme Board of Health of Mexico.

these cases are comparatively rare and they are so with yellow fever. This immunity is acquired after repeated attacks, as well as mild ones, and even when the attacks have been abortive.

Other persons who also enjoy immunity from the disease, are those who have been born in those places where yellow fever is *endemic*. This immunity is so general that Dr. Heinemann had made use of it to establish the difference between the regions where the disease is endemic and which are in this paper considered as *centres*, and all those other places which present favorable conditions to the development of the disease *when imported*, but in which it does not spontaneously engender. Nevertheless, this immunity is not by any means absolute, as the physician whom I have quoted mentions cases of persons who had been born and had lived in Vera Cruz, and who nevertheless had been attacked by yellow fever. Similar observations have been made by other physicians of Vera Cruz, who are worthy of all credit.

The immunity can in some cases, although very rarely, be lost, when the person who enjoys it has been absent for a longer or shorter period from the locality. The time required to elapse before the immunity is lost is very variable.* Dr. Garmendia relates the case of a relation of his own who was born in Vera Cruz and lived there. He remained in Europe for three years, and on his return suffered an attack of yellow fever that put his life in danger. A gentleman of advanced age who for many years had filled the position of director of the military hospital, was attacked by yellow fever after having passed some years in Jalapa and in the Capital of the Republic.

As I have before stated, Dr. Heinemann considers, that *the immunity of the natives in any locality where the yellow fever reigns in an endemic form, is the criterion to guide us in classifying the endemia.*

"In a town in which yellow fever had been prevalent for many years," he says, "the natives acquire an immunity, but if for another series of years the disease should not appear, the natives will lose the immunity they have acquired." A proof of this is found in what happened where epidemics appeared in 1843, 1847, 1848 and 1853. Up to that time the epidemics attacked both foreigners and natives of the locality, but in the epidemics of 1863 and 1864, the natives had acquired that immunity and therefore escaped. But after the year 1878, they had lost this immunity, as is proved by the fact that Dr. Hegevich, physician of the Military Hospital in Vera Cruz, attended several soldiers who were natives of Tampico, and who contracted the disease in that port, besides the son of a merchant in Tampico who had removed his business house to Vera Cruz.

I venture to give an explanation of this fact, which appears so extraordinary to Dr. Heinemann, whose opinions I have quoted in the preceding paragraph.

Starting from the unquestionable fact, that an individual who once undergoes an attack of yellow fever is afterwards safe from this disease; that this immunity is enjoyed both by those who have suffered from severe attacks, as well as those who have only had slight attacks, and even by those persons in whom the disease had presented itself in an abortive form, taking for granted the fact that in those localities in which the disease had prevailed for many years, the natives acquire that immunity in the course of time, which they afterwards lose if the disease has not appeared for another series of years, we can base the hypothesis, that all those persons who enjoy such immunity have acquired it by previons attacks which have generally been of a mild character, sometimes abortive, or, perhaps, in the earliest infancy. This hypothesis is supported by the practice of many ladies, who finding themselves absent from the localities in which yellow fever reigns in an endemic form, returned to those localities previous to their confinements, with the object of placing their children in a position to acquire that immunity. The idea that I am presenting is not only my own, but is also largely supported by many physicians of Vera Cruz.

The conviction that mild attacks of diseases which can only be taken once in a lifetime, form a safeguard against any graver form of the same disease, is what induced physicians to inoculate persons with a mild form of small-pox, as a precaution against the real and dangerous disease, until the admirable discovery of Jenner demonstrated the possibility of

* Dr. Garmendia, quoted by Dr. Heinemann.

rendering men safe against that terrible scourge. In later years we have seen the wonderful discoveries of Pasteur, and following his footsteps, we have earnest workers from all nations, laboring night and day in patient investigation and scientific experiments, all directed to procuring the immunity of men and animals against certain diseases. This brings me to speak on the question of preventive inocnlations.

Neither I, nor any of my colleagues from the Mexican Republic have any experience with regard to the practical results of the inoculations made by Dr. Freire, of Brazil, and, therefore, I shall confine myself to those which have been practiced by Dr. Carmona y Valle, of Mexico. This friend and colleague of mine, published in the year 1885, his clinical lectures on the etiology and prophylaxis of yellow fever, and with the object of procuring the immunity of those persons who might be disposed to contract the disease he proposed to inoculate them under the skin with a mixture of one gram of distilled water to one or two grams of residue of the urine from yellow fever patients, which had been submitted to spontaneous evaporation, so as to obtain a dry deposit. After numerous experiments on animals, Dr. Carmona inoculated himself as well as other persons who voluntarily presented themselves to help him in his experiments. The results having convinced him of the inocuousness of the method, he inoculated persons who were going from Mexico to Vera Cruz, Havana, or the Pacific Coast, which, at that time, was being ravaged by yellow fever. The greater part of the persons inoculated escaped the disease, but a few were attacked and some even died. The experiments were, therefore, not of a decisive character. In order to give it this character, it was proposed to make comparisons of the mortality caused by yellow fever amongst the convicts living in the penitentiary of San Juan de Ulua, on an island in the port of Vera Cruz in front of the city, and the soldiers who should be previously inoculated by this system, from the garrison of Vera Cruz. Both these classes of men are taken to Vera Cruz from the more elevated parts of the Republic, they are not acclimated, and mostly belong to the same social status.

The number of sick people admitted into the civil and military hospitals of Vera Cruz during the months of January to May, 1885, as well as the comparative table of the sick who came from the penitentiary and the soldiers of the garrison, *who had been previously inoculated,* are set forth in the works of Dr. Carmona.* A study of this work shows us "that during the five months of the year in which the epidemic raged, the convicts who were attacked numbered 72, being 41.52 per cent., whilst the number of cases amongst the inoculated soldiers only came to 26 or otherwise 6.84 per cent."

It might be objected that the conditions of life and the moral condition of the persons submitted to the experiment, are not similar, but Dr. Carmona also presents the testimony of 174 soldiers who arrived in Vera Cruz at the end of July of that same year and who had not been inoculated or acclimated. These soldiers came from the State of Tabasco where they had been living in a climate as hot as that of Vera Cruz. This group could very fairly be compared with that which was formed by the garrison of the place, the soldiers of which had been inoculated.

The following were the results: In three months there were 56 cases in the first group or 32.18 per cent., (it must be remembered that in the group of convicts the percentage was 41.62), which makes us believe that if the observation had lasted as long as the other, *i. e.,* five months, the percentage would have reached the 41.62.

From these facts we can infer that inoculation and not the hygienic conditions was what caused the least proportion of cases. Notwithstanding that these facts have been known, no experiments have been made either in the Republic or abroad, but I believe that it is now time to again experiment in order to find out their true value. Had we not been convinced of this, we would have become so by reading what the eminent Dr. Geo. M. Sternberg† says in his review. He says: "According to the results to which we

* Lecons sur l'Etiologie et la Prophilaxie de la Fievre Jaune, Mexico, 1885. De quelques faitsrelatifs a la Fievre Jaune, Rapport presente parle Dr. Cormonay Valle.

† Inoculation for contagious diseases. Preliminary report of the Committee of the American Public Health Association.

refer, the writer has thought that inoculations as practiced some years ago by Dr. Carmona y Valle, of the city of Mexico, may have rational bases." He adds: "Lacking the knowledge of the infectious specific agent of yellow fever, two methods are presented which may obtain immunity by means of inoculation. The first method is to follow the experiments of Professor Carmona, by which a sufficient quantity of specific toxalbumin of yellow fever is introduced, under the supposition that such substance exists in the blood of patients during the progress of the disease.

"The second method is to introduce into the circulation of the susceptible person the antitoxin of yellow fever, which, if we reason by analogy, is to be found in the blood of persons who enjoy immunity. In the experiments made to determine the possibility of establishing immunity by the first method we should propose that the urine shall be evaporated rapidly in vacuum."

As it will be seen, Dr. Sternberg recommends the inoculations of Dr. Carmona. Accepting the hypothesis that the urine of yellow fever patients may contain specific toxalbumin which might produce immunity. This hypothesis is strengthened by the demonstrations of Dr. Bouchard of France, which show that what is so inoculated is eliminated through the urine. As I have demonstrated that the only way to have immunity is by having had the yellow fever, if we succeed—with Dr. Carmona's inoculation—in introducing a substance which shall produce immunity, then we shall have obtained the same results as vaccine in small-pox. With the idea of scientific principles which modern science has reached, the inoculations of Dr. Carmona should be tried again, making the rapid evaporation of the urine in vacuum as recommended by Dr. Sternberg, and as experience has demonstrated that they are harmless, and easy in their technic, they should be made simultaneously in all countries where yellow fever exists or is liable to be introduced. Were results to be published in an uniform manner, in blanks printed for the purpose, by the yellow fever committee, then we would soon find out whether the inoculations have any value or not. If results justify the practice, we shall have obtained immunity for the people who are compelled to live in those places, and if not the second method should be tried, *i. e.*; the one proposed by Dr. Sternberg; the inoculation of blood secured from persons already immuned.

As prophylactic means, I recommend the purification of the drinking water, for Dr. Gavino, Professor of Bacteriology in the Medical School of Mexico, has observed that in Vera Cruz the people who drank well or cistern water or others kept in such a way as to become impure, were more liable to the disease than those who drank the water of the Tampa river when it had not been contaminated. The same professor, on examining the drinking water of Vera Cruz, found an unknown bacterium, which liquifies gelatin and congregates in oval colonies of a yellowish-greenish color which reminds us of the color of yellow fever patients.

He examined the liquid from the intestines and found a bacillus of the same character, but shorter than the one found in the water. This similarity and the fact that bacteria was not found in the liver, spleen, kidneys or blood made him believe that yellow fever is an intestinal disease. Were this to be confirmed, the purification of water wonld be an absolute necessity. but if it is not confirmed it will be of benefit to those who drink it.

The last subject which I propose to study is the means by which we can prevent the importation of yellow fever. This is a most important point when we consider that if the methods of which we have spoken will some day prevent the disease, the measures which we are going to propose, strictly enforced, will not only prevent the disease from spreading out of the present epidemic centers, which are few, into the great territory of our Republic, which although it does not originate the disease, is very fertile to receive it, but what is still better, the measures proposed will prevent the disease from being imported to our centers in the seasons when there is no fever. This could not be called an ideal, because it is a known fact that many doctors and historians believe that yellow fever was imported to Vera Cruz, our principal center, more than three centuries ago. What happened in New Orleans is the best proof of the assertion, for that port was a center of infection, from whence it was taken to Tampico, as we have already said, and

the fever has not shown itself for the last fourteen years, since the port has been closed to vessels from infected ports. The measures which I proposed are founded on the two great resources placed within our reach by hygiene : *Isolation and disinfection*, applied not only to vessels coming to infected ports, but to those leaving the said ports. Having reduced to a minimum the harm which all sanitary measures generally bring to commercial interests and communications, we have not forgotten that *Salus populi suprema est lex.* The measures are as follows : Landing and isolation of the sick ; keeping passengers who may be suspected and who land under observation for seven days and allow those who will not submit to observation to proceed to places over 1,000 meters above the sea level. Disinfection of the ship or the ports which may have become infected. Disinfection of ship's manger and fresh water supplied. Disinfection of all wearing apparel, baggage and merchandise liable to infection, especially packing cases. These measures are not to be so strictly enforced if the ship has no sick on board on arrival, if it has no merchandise liable to infection, or if it has on board a disinfecting apparatus and a doctor.

CONCLUSIONS.

1. The places where yellow fever reigns and which can be considered as centers of infection are in the Gulf of Mexico, Vera Cruz, Frontera, Campeche and the districts on the districts on the northern coast of the Yucatan peninsula, the last named separated by the Yucatan canal from the island of Cuba, where the fever also reigns. On the great Pacific Coast, which belongs to the Mexican Republic, there is not a single yellow fever center.

2. All the Mexican territory of the Gulf of Mexico and on the Pacific Coast is well adapted for the disease when imported.

3. Yellow fever has become epidemic in the following places of the coast on the Gulf: Matamoros, Altamira, Tampico, Tuxpan, Papantla, Misantla, Nautla, Alvarado, Coatzacoalcos, Minatitian, Lagang; and San Juan Bautista de Tabasco.

4. The epidemic has extended into the interior, but never into ploces situated more than 1,008 meters over sea level.

5. On the Pacific there is not a yellow fever center, but it has been imported into the following places: On the peninsula of lower California, La Paz y Todos Santos; on the Continent, Guaymas, Altata, San Blas, Manzanillo, Acaponeta, Acapulco, Puerto Angel, Salina Cruz Tonala Soconuzco, Tapachula, and San. Benito, and in the interior in Hermosillo y Culiacan.

6. Immunity against yellow fever is obtained after having had the disease in any of its forms. It is possible that this immunity may be lost at times, but it is seldom the case, as it happens with typhus, small-pox and scarlet fever, which may be had by a person who has had them.

7. The vaccine of Jenner against small-pox and others which science has discovered, authorize us to look for the one that will prevent the yellow fever. The inoculations against this fever which Dr. Carmona y Valle has practiced with success should be tried on a large scale, in an uniform manner, in order to be able to find out if they are efficacious or not. If future experience should confirm them, then they should be made compulsory in the countries where the fever reigns. If they should not prove worthy, then the inoculation with blood serum, as proposed by Sternberg, from persons enjoying immunity, should be tried on a large scale and in an uniform manner.

8. The purification of the drinking waters used by persons who have to expose themselves to contact the disease, should be recommended. The purification of the water used on board the ships leaving or calling at infected ports should be proposed.

9. The sanitation of the places which are yellow fever centers should be done at once.

10. To prevent, by means of sanitary police measures, the importation of fever into places where it can be developed.

## SOME PRACTICAL POST-MORTEM POINTS.*

HENRY W. CATTELL,† A. M., M. D., Philadelphia, Pa.

1. Get all the anatomical knowledge you can out of every autopsy you make. It is, therefore, usually advisable, especially in the case of females, to perform a preliminary laparotomy. Many surgical operations can be practised upon the body without disfigurement, such as Alexander's operation, oöphorectomy, removal of the ear ossicles, and vermiform appendix, stretching of the sciatic nerve, symphysiotomy, etc.

2. Do not forget to dictate the post-mortem notes while the autopsy is in progress.

3. Respect the feelings of the friends in every possible manner, and always return everything in a private house to its proper place. Be sure to leave no blood marks behind.

4. Be sure you have a legal right to make the post-mortem before you begin. The nearest relative, or the one who is going to pay the expenses of the funeral, should give the consent in writing.

5. Do not take away more tissue from a post-mortem than you are able to thoroughly work up.

6. Try to encourage a demand among the laity for the performance of autopsies.

7. In making an autopsy have a regular method for its performance, which is only to be modified by exceptional circumstances. Finish the examination of each organ in as thorough a manner as possible before the examination of another is commenced.

8. Label all your specimens at once with name of person from whom the specimen is removed, character of the specimen and relations in the body, date, and preservative fluid employed.

9. If you are so unfortunate as to cut yourself, wash the wound with running water for four or five minutes, and then dress antiseptically. Do not, out of bravado, go on with the post-mortem, if there be anyone else present who can complete it.

10. If you are not making the autopsy yourself do not be too forward in making suggestions to the one who is making it; but always be ready to do anything that you are asked to do in connection with the autopsy.

11. Let your medical friends enjoy the autopsy and specimens with you.

12. Get all the posts you can; never refuse to make an autopsy for another, when you possibly can.

13. Tact will get you many autopsies; curiosity of relatives and friends can often be worked upon to get permission for an autopsy.

14. As the object of the autopsy is usually to find out the cause of death, either for legal or scientific purposes, the post-mortem should, therefore, be conducted in as thorough and accurate a manner as possible.

15. In legal cases be sure to protect yourself in every possible way. The jars (which should never have been used) containing the specimens, should be sealed in the presence of a witness. In important cases here in Philadelphia, the Coroner has both of his physicians present at the autopsy, so that the testimony is stronger; and in case of absence of one of the physicians the other can go on the witness stand and the case not be postponed.

16. If you value your peace of mind do not put yourself forward as an expert witness in medico-legal matters. Knowledge which you already have should be freely given to the court in criminal cases, but the court cannot compel you to obtain expert knowledge without your consent.

17. In Germany the legal evidence of a post-mortem held by gas-light has been judged by the court, except under certain peculiar circumstances, to be void.

18. If two persons are lifting the body the lightest weight is at the feet.

19. Chloroform, when placed on a towel and the head enveloped in the towel, will quickly dispose of pediculi capiditis.

20. Many signs of inflammation, especially of the mucous membrane, disappear after death. Remember that red flannel often colors the skin red.

---

* Read before Philadelphia County Medical Society, October 25, 1893.

†Demonstrator of Morbid Anatomy in the University of Pennsylvania.

21. Make the undertaker your friend. Do not recommend an undertaker who disapproves of post-mortems.

22. It is a good knife that will keep its edge in more than one post-mortem.

23. Do not jump at conclusions too quickly. Tentative diagnoses alone should not be made until the post-mortem is complete.

24. Always weigh the important organs, and have some method by which you can tell the right from the left organ in case of the double ones. One nick in the left-sided organs and two in the right will readily distinguish them.

25. Wash your hands frequently during the performance of an autopsy so as not to allow the blood to dry on the skin.

26. In opening a cystic kidney be careful that the liquid does not injure the eyes or soil the linen, as when the kidney is opened the liquid in the cyst is under pressure and may squirt several feet.

27. A duct can often be easily followed by making a nick in it, and then introducing a piece of broom stick or a groove director in the direction you desire to dissect. This is especially useful in the ureters and the ductus choledochus communis.

28. In writing the account of an autopsy describe what you see; do not use names of diseased conditions. These should be put in under the head of pathological diagnoses.

29. Urine, or aromatic spirits of ammonia will best take off the odor from your hands. This odor is usually gotten from opening the intestines.

30. Ammonia (also the aromatic spirits) will remove iodide stains; a weak solution of the hypobromite solution will remove carbo-fuchsin and other aniline stains from the hands.

31. Any organ which you desire to save should be placed in a safe place so that it will not be returned to the body and sewed up.

32. The dissecting-room is a poor place to study pathology, on account of the chloride of zinc forming with albumen an insoluble albuminate of zinc.

33. Nervous tissue for microscopic study should not be placed in zinc chloride or in alcohol.

34. Remember that a post-mortem, with the exception of the brain and cord, can be made with a penknife.

35. Remember that the thoracic and abdominal organs can be removed by the rectum or the vagina.

36. Before removing the calvarium have a basin so placed that it will receive the blood and cerebro-spinal fluid.

37. Drawings, photographs, casts, cultures of micro-organisms, and microscopic slides are valuable additions to a well written account of an autopsy.

38. A lesion in one part of the body will often suggest a careful search for a lesion in another part of the body.

39. Do not mistake the normal for the abnormal.

40. Squeezing the gall-bladder after the duodenum has been laid open, will often cause bile to pass out, and the papilla, the ending of the common bile-duct, can thus be demonstrated.

41. Remember that frozen sections of fresh tissue can be cut and mounted in a half hour to an hour.

42. Three hours is none too long in which to make a complete autopsy.

43. Be careful that the first rib does not scratch your hands when removing the tissues in that region. Therefore cover over the cut-ends of the clavicle and ribs with the skin flaps.

44. Blood makes a good glue for affixing labels, and the blood of a person dying from hydrocyanic poisoning makes a most excellent red ink which will keep for years without the addition of any preservative fluid.

45. Remember that after the brain has been removed that the fundus of the eyes can be removed by a circular incision posteriorly, without disfigurement. The inside should then be stuffed with dark colored wool or cloth.

46. In private cases you will be frequently judged of your skill as a pathologist by the neatness with which you sew up the body.

47. If you discover suspicious lesions always stop the post-mortem and report the case at once to the Coroner.

48. Remember in warm weather that the intestines are especially liable to undergo rapid decomposition when exposed to the air.

49. Remember that a railway train or cart may pass over the body and there be no abrasion in the skin more than a brush burn.

50. Remember that the color of organs is frequently changed when exposed to the air by the oxidation of the hæmaglobin. Also that the sulphide of iron frequently discolors organs after death, due to the sulphuretted hydrogen during decomposition precipitating the Fe. of the hæmaglobin.

51. The clavicle can be grasped and moved and the claviculo-sternal articulation thus readily discovered.

52. In removing the cord the following method may be used without disfigurement to the skin of the back part of the neck. Make a circular incision from the middle of the trapezius muscle of the one side, to the middle of the same muscle of the other side, using as the centre of the circle the external occipital protuberance. This will take you in the median line to about the second dorsal vertebra; then dissect away the skin with muscles attached, and elevate this flap with a tenaculum and draw the shoulders backward. A sufficient amount of space will be given to then remove the cord in the usual manner.

53. If the rectus muscle on each side be cut near its origin, in the direction of Poupart's ligament, the abdominal cavity will be much more thoroughly exposed to view than in the ordinary manner. First, however, examine with the finger for hernia.

54. And lastly be honest. Everyone diagnoses lesions during life which are not found at the post-mortem. Even after a most careful post-mortem it is often impossible to tell from what the patient died.

---

## LARGE DOSES OF STRYCHNINE IN THE TREATMENT OF PULMONARY AND CARDIAC DISEASES.*

THOMAS J. MAYS, A. M., M. D.†

From quite an extended experience with the use of strychnine I feel convinced that this drug gives better practical results in the treatment of pulmonary and cardiac diseases than any other single remedy at our command, and it occurred to me that a short discussion of the principles which I have followed in its administration might be of interest to the members of this Society.

It is needless to tell you that strychnine has a more powerful stimulating influence over the nervous system than any other drug in the materia medica, and that besides its general action it has a special influence on the nerve supply of the lungs, heart, stomach, intestines, etc. Now, without going into details, it is my belief that many affections of the lungs and heart are fundamentally dependent on disorder of the nerves which supply these organs, and that the curative effects of this agent in these diseases rest largely on the power which it has in correcting this primary aberration. Over and above this it has been recently shown that strychnine also has the faculty of multiplying the corpuscular elements of the blood, and is therefore, like iron, a blood-builder. A combination of such valuable properties in a single agent makes it apparent on theoretic grounds alone why strychnine should possess such a beneficial therapeutic effect in the diseases which we are here considering, since anæmia is one of their most common complications. In spite of these desirable qualities I believe that we often fail in obtaining its best effects by giving it in doses which are entirely too diminutive. I do not mean to say that strychnine should be given in large doses in every disease to which it is applicable, for such a statement might lead to great harm if it were practically carried to its legitimate end, but these remarks pertain only to those diseases to which reference is made in this paper. The custom of giving strychnine in doses of $\frac{1}{60}$ or $\frac{1}{30}$ of a grain I have discarded long ago, for I feel satisfied that such amounts are comparatively worthless. It is very rare that I begin with a smaller

*Read before the Philadelphia County Medical Society.

†Professor of Diseases of the Chest in the Philadelphia Polyclinic, and visiting physician to the Rush Hospital for consumption.

dose than $\frac{1}{32}$ of a grain, and more often with $\frac{1}{30}$ of a grain, and then gradually increase in an ascending scale until I touch the limit of toleration. Strychnine is peculiar in this respect. The length of the ascending scale from the effects of such a dose to a point where the physiological action of the drug begins to develop itself is usually very long, and during the time that this is traversed by the therapeutist a free opportunity is given in which to obtain the full stimulant action of the drug in gradually increased doses. I usually incorporate one grain of strychnine with phenacetin, quinine, etc., and divide the whole into thirty-two capsules, and give one capsule four times a day. This lasts eight days, and then $\frac{1}{8}$ of a grain more of strychnine is added to the whole quantity, which is thereafter increased $\frac{1}{4}$ of a grain every eighth day until the limit of toleration is approached. This varies very much in different individuals. I have a number of patients under my care at the present time who are taking $\frac{1}{10}$ of a grain, and four who are taking $\frac{1}{5}$ of a grain, and one who is taking $\frac{1}{3}$ of a grain four times a day. Most of these patients have been taking the drug from three to seven months continuously. I have seen patients, however, who could not endure more than $\frac{1}{20}$ of a grain four times a day. So soon as the patient begins to show evidence of intoxication the dose is reduced to a point where this is no longer manifested, and then maintained there permanently or again increased after some time. It is possible, however, and this should always be borne in mind, that the dose which was toxic once may in time be taken with impunity. This would seem to show that the poison line of strychnine recedes, and that the drug establishes a certain degree of tolerance for itself. Yet I have met with one case where the administration of the drug was broken off for almost two weeks, and then, on resuming the same dose which was previously taken, marked rigidity of the lower limbs followed after the first two doses.

What, if any, are the untoward effects of strychnine when given in such large doses? So far as I know there are none except its occasional tendency to produce diarrhœa; but at the very worst I do not believe this proneness is very pronounced. In my earlier acquaintance with it I fancied that it aggravated the diarrhœa which is such a frequent accompaniment of phthisis, but my later experience fails to confirm this, since I have seen cases of intestinal tuberculosis get well when strychnine was given in combination with morphine and oxide of zinc. It has been asserted that it causes albuminuria by reason of the high blood tension which it brings about. Of this I have not the least evidence, having frequently examined the urine of patients to whom strychnine had been administered in such large doses for more than a year.

I will now briefly consider in greater detail the mode of giving strychnine in each disease to which it is believed to be applicable. In *asthma* I usually begin by introducing $\frac{1}{60}$ of a grain under the skin, and administer about $\frac{1}{30}$ or $\frac{1}{25}$ of a grain by the mouth four times a day, and gradually increase this in the way above indicated. Hypodermatically it is given once a day or every other day, and if possible in the evening, until there is an approach to the toxic effects of the drug. Suitable doses of phenacetin, quinine, capsicum, and ammonium muriate will enhance its action. So far as my experience goes strychnine must be regarded as the most powerful adjuvant in the treatment of asthma, although we must never lose sight of the importance of treating the diathesis or exciting cause on which the disease often rests, and also of improving the general nutrition.

*Bronchitis,* whether acute or chronic, is very much benefited by strychnine. It checks the cough, diminishes the expectoration, improves the appetite and puts to one side the whole constitutional relaxation and feebleness frequently present, especially in the chronic form of this disease. It must be given in ascendant doses, and may be combined with benefit with the syrup of hypophosphites or hydriodic acid, or with both.

Strychnine is one of the most useful agents in treating acute pneumonia, whether this is of the croupous or catarrhal variety. I usually begin by injecting $\frac{1}{60}$ of a grain every three or four hours until symptoms of intoxication begin to show themselves. This I have seen to take place on the second and third day of the disease. If the case is a mild one it will suffice to give $\frac{1}{60}$ of a grain every four hours.

I know of no disease which is more eminently benefited by strychnine than pulmonary consumption. Indeed, as a rule, it seems that sufferers from this disease are capable of taking this drug in extraordinary large doses. I have a number of phthisical people under my care at the present time, both in hospital and in private practice, who are taking over half a grain of it a day—a dose which had been reached by a gradual increase of a smaller one. For a more complete description of the use of strychnine in primary pulmonary diseases I would refer you to a paper of mine on this subject, contained in *The Medical News* of July 22, 1893, and the remainder of this paper will be devoted to cardiac and cardio-pulmonic diseases.

In recommending strychnine as one of our most valuable cardiac stimulants a fear may spring up in the minds of many that this drug is put forward for the purpose of displacing digitalis—the old and well tried heart-tonic. That such a suspicion is not altogether groundless when held by those who prescribe digitalis for almost every phase and form of heart disease they meet, is true; but he who looks the question of cardiac therapeutics squarely in the face, feels, although more perhaps from an instinctive than from a scientific standpoint, that the action of digitalis is not interchangeable with that of strychnine, and that each fulfils its own peculiar indication in the treatment of diseases of the heart. Although we may not be able to draw a rigid line of demarcation between the behavior of these two agents, we have experimental evidence to show that digitalis acts more on the muscular and less on the nervous structure of the heart than strychnine. My own experiments demonstrate that digitalis enhances or increases the irritability of the heart muscle, while strychnine depresses or reduces it; and that that the former arrests the heart in systole while the latter arrests it in diastole. It is my belief that the action of these drugs is as dissimilar clinically as it has been shown to be physiologically, and that strychnine is principally indicated in these diseases of the heart which are dependent on a disturbance of innervation, as for example, in simple cardiac weakness and in irregularity and intermittency of its pulsations, while digitalis is preferable in cases where there is a want of compensatory power in the heart muscle, as in valvular incompetency.

Bearing in mind this difference, strychnine should be prescribed when the nerve supply of the heart is enfeebled through auto-intoxication such as is found in the post-paralysis of diphtheria, scarlatina, measles, smallpox, influenza, whooping-cough, and in poisoning from alcohol, lead, mercury, etc.

Irregularity and intermittency of the heart's action are frequently benefited by the administration of large doses of strychnine, and more often than not, do we find that digitalis is utterly useless in such cases. Sometimes the irregularity will remain even under the influence of strychnine, but the symptoms which are dependent on or are a part of this condition, such as pain in the precordium, orthopnœa, oppression of the chest, will improve or disappear, especially if suitable evacuant remedies are used at the same time. This whole disorder I regard as being probably due to a want of power in the discharge of nerve-force of the heart or rather, perhaps, to a lack of nerve-control over the discharge of the muscle force of the heart. This weakness of nerve-power is not only marked in the heart, but it is also apparent in the lungs and frequently manifests itself, especially in elderly people, in a co-existent œdoma of the bases of both lungs.

Moreover, there is often found an irregularity or intermittency of the heart's action in severe seizures of asthma, and I know of nothing which will remove this accompaniment, as well as the original disease, as strychnine in large doses promptly administered, both hypodermically and by the mouth.

Angina pectoris is another paroxysmal disease in the treatment of which strychnine in large doses stands pre-eminent.

Again, digitalis is always regarded as the sovereign remedy in the treatment of valvular diseases of the heart and their sequences, but there comes a period in the life history of every such affection in which digitalis, no matter how much benefit was derived from it before, proves utterly useless. This leads of course to disappointment, and often gives rise to serious suspicion concerning the utility of this important agent. The fault lies, however, not in the drug, but in its improper application. It has done all that

could be reasonably expected of it. It stimulated the heart muscle to renewed activity after the valvular rupture occurred. It aided in developing its muscular fibres and restored its former power; but now, for some reason or other, the nervous energy of the patient begins to flag, and the heart-walls commence to relax in spite of the muscular hypertrophy which is present, and digitalis no longer possesses the spurring properties which it once had. The blood dams up in the left ventricle and auricle, the pulmonary circulation becomes impaired, œdema and congestion of the lungs follow, and death is threatened by way of the pulmonary organs. It is at such a time, when digitalis fails to counteract these many incidental complications, that strychnine steps in and shows its superior value as a tonic to the waning nerve energy of the heart and lungs.

## PRIMARY PERINEAL OPERATIONS.

MORDECAI PRICE, M. D., Philadelphia.

There is no subject in obstetrics or gynecology that demands our immediate attention more than vaginal tears after delivery. These may be of serious nature, demanding of the attendant skill and training in this branch of our obstetric art but few men have attained, but one in which all must operate. No one can be excused for leaving the work for some one else. It is his to do and at once. If he can get help all the better, but do the operation he must. It is a very common mistake of men attending women in childbed, no matter how difficult or complicated the case may be, to consider his work complete as soon as the child and placenta are delivered and the woman washed and made comfortable in bed. He makes no effort to find out how much damage or injury has been done to uterus, vagina or perineum. He orders a vaginal douche and leaves his case to Providence. Fortunately for the poor woman, Nature does wonders for her restoration.

In bringing to your notice this subject, I desire only to present my own experience and to emphasize the importance of careful vaginal examinations after labor. Injury may occur at any time from the dilatation of the cervix to the expulsion of the child. The cervix may be torn to the opening of the peritoneal cavity; the vagina torn from the cervix, or down the median line and, including the bowel, from the cervix to the sphincter; or the line of rupture may be to the side in the sulci, and extend very deep into and including the sphincter. Most of the sulci tears are inside leaving the fourchette in its natural position and without careful examination after delivery, no one would suspect the perineum had been injured. Yet some of the worst injuries to the pelvic floor are altogether inside, even the bowel and bladder may be opened without any tear on the outside. Then we may have the vagina torn transversely as the head crowds the walls before it in labor. These tears may extend through the entire septum to the bowel, and there are cases where the child has been delivered through the bowel. So you can comprehend the terrible accidents to the soft parts of the mother in labor are to be in the first place avoided if possible and if not, the immediate repair of the injury is demanded as soon as the labor is finished and before the woman is placed in bed for rest.

These accidents depend upon the violence or amount of force used in the delivery, or the conditions of the parts at the time of labor, or to deformity of the mother, size of child or the duration of the delivery. Under this last head will come unavoidable delays and unnecessary haste in the delivery of the child. What might be delay in one case would not be in another, as the conditions of both mother and child may be entirely different. All these conditions must be considered by the attendant who conscientiously does all he can for his patient.

In labor nature should have her own way so far as is consistent with the safety to both mother and child. To treat in any other way than this would be to encourage the very accidents we most

anxiously wish to avoid. Many, probably the larger number, of accidents occur in the first labor, and in women about the midway period of menstrual life. These do not bear the pains and suffering incident to maternity with the fortitude of their younger sisters, so that age of the mother in primiparæ should have an influence in our care of the case.

We will take for granted that all has been done to prevent the accident we now propose to repair and there only remains for us to do the work in a most workmanlike manner so as to get the best result.

Immediately after delivery in a patient with ruptured cervix or perineum, the patient should be so placed as to give the best light and be convenient and comfortable to the operator; the parts injured examined and carefully washed with hot antiseptic solution. If the injury be of the cervix, with the aid of a Sims' speculum, the parts should be carefully coaptated with silkworm-gut sutures, shotted and the parts again washed with an antiseptic solution—the best in my opinion being bichloride of mercury. The stitches of silkworm-gut may be left in place with perfect safety until the mother is ready to leave her bed. The perineum should be examined in the same careful manner and closed with the same material (silkworm-gut.) To prevent the frequent handling of the parts during recovery, the stitches can remain for weeks. If silk or thread be used, the stitches act as irritants after the third or fourth day, and should be removed. This is the best way to close a ruptured perineum.

If the rupture is completely through the septum and sphincter, then the sutures are placed a little differently but with the most painstaking care, for in a case of this kind failure means great suffering to the patient and discredit to the attendant. When the rupture extends through the bowel, the finger should be passed into the bowel as a guide and the first stitch should be at least three-quarters of an inch above the tear in the bowel and from that point down four stitches to the inch inserted. Entering the needle a quarter of an inch from the torn ragged edge, including as much tissue as possible in the grasp of the needle, with the point of the needle in the direction of the opposite side of the operator, emerging at the very bottom of the tear and then entering again at the same point, pass backward at the same angle to the opposite side and emerge at the same distance from the torn edge. If the tear is through the bowel, the stitch should come as near the torn edge as possible. If the tear is ragged, take more of the margin so as to have the stitches as near in line as possible, and as you approach the external margin you will have to place your stitches so as to include the sphincter. Three to four stitches on the outside will greatly help to perfect the operation. The sulci tears should be closed in the same careful manner. The torn surfaces should be washed with hot antiseptic fluid, or at least with hot water, and carefully dried before shotting the silkworm-gut. If all the discharges are removed and the stitches closed with care, remembering that we will have more swelling in primary operations than in the secondary, we will have the most gratifying results. I have never had one fail to unite by first intention. Use care in doing your work and you will never regret primary closure of the tears in childbed, and will be the means of saving many valuable lives from sepsis and the helpless conditions following culpable neglect of the first principles of obstetric and gynecological surgery, as laid down by the best teachers on this subject.

*Case No. 1.*—Mrs. W., twenty-three years old; married. Patient of Dr. Judd. When married was of slender build and rather a delicate girl. She became pregnant soon after marriage and began to increase in flesh, and at time of delivery weighed some forty or fifty pounds more than at time of marriage. The labor was an exceedingly difficult one and rather protracted. No instruments were used. The soft parts dilated slowly and imperfectly; the child was a tremendous boy with a well-formed, hard head but slightly reduced by the moulding process. Two fingers filled up the external outlet when the head was well down in the pelvis. Dr. Judd fully expected a torn perineum and sent a messenger asking my assistance in its repair. The delivery was already accomplished when I arrived and the perineum was torn clear through both internal and external sphincters, the full length of my finger. Every effort was made by her attendant to prevent injury, but it was one of those cases

where nothing can save the perineum; nothing dilates as it should and when the head passes it must do so over torn tissues. Owing to her great increase of flesh it was impossible, no matter in what position we placed the patient, to bring the torn parts into view. A long perineal needle threaded in the usual manner to place the silkworm gut sutures was used. In this case the sutures had to be placed entirely by the sense of touch, the needle carefully adjusted in the needle holder, needle and holder were passed up into the vagina, and the forefinger of the left hand used to find the vaginal surface and direct the point of the needle as far back of the torn ragged edge as possible so as to bring as much vaginal tissue in the grasp of the suture as possible. Then passing the guide finger of the left hand up into the bowel and passing the needle directly through to the bottom of the tear, which at this point only extended to the walls of the bowel, I put as many sutures as possible at this point and as I came down included the margin of the bowel clear to the sphincter, as in the Emmett operation for complete laceration.

One of the secrets of success in this operation is the use of plenty of tissue. The ragged vaginal wall does not need to be trimmed, but closed just as it is found. In shotting the sutures we must remember the parts are torn, not cut; that they have been greatly injured and bruised in the travail; that in the shotting of our sutures we must use great care so as not to make too much constriction of the tissues. Nine silkworm-gut sutures were used in this case and were removed on the eleventh day. Patient's bowels were kept soluble daily. She made a most beautiful recovery, the perineum uniting in every part. Dr. Judd informs me her condition afterward was most satisfactory.

*Case No. 2.*—While this was a complete rupture of the perineum, it was entirely different from the one just reported. Patient of Dr. Rishel. Nineteen years old, married, suffering from chronic Bright's disease, pregnant with her first baby. When the Doctor was called she was in active labor and in convulsions. The cervix was sufficiently dilated for him to apply the forceps, which was done at once with the patient under chloroform. A messenger was sent for me, but I arrived after the delivery. The Doctor said the patient had been torn but he had not made an examination. His entire attention had been given to the desperate condition of the mother. I carefully examined and found the perineum torn through, and up the bowel for fully an inch above the external sphincter. In this case the wound could be easily exposed and the stitches placed. Seven were used—two above the rectal tear, five in the rent in the bowel and to coaptate the sphincter. Patient recovered very slowly from the convulsions. The wound healed leaving a slight fistula for several days and then closed entirely.

At times one or more of the stitches leave a fistulous tract but they soon close without help. I think the trouble in this case was from the advanced Bright's disease, which left the patient in a debilitated condition that did not favor rapid healing. The stitches were removed on the twelfth day and everything appeared well closed. I have no doubt the condition of her kidneys will prove too much for her recovery.

All tears in the perineum, unless a mere scratch, should be closed carefully at the time of the injury. They give but little trouble to the attendant and cause the patient very little pain as the parts are in a benumbed condition. But if left only a few hours, to close them without ether would be most cruel and the probability of immediate union not so good. All this work should be attended to at once, the instruments necessary—a small needle and thread—can be found in any house, but the best way is to have such instruments with you. Silkworm-gut for sutures and perforated shot and a shot compresser, which is also a needle holder, is the best, requires but little room and can be obtained at slight expense.

---

**Not In It.**

He has no enemies, you say.
My friend, your boast is poor.
He who hath mingled in the fray
Of duty that the brave endure
Must have made foes.
If he has none,
Small is the work that he has done.
He has hit no fraud upon the hip;
He has shook no cup from perjured lip;
He has never turned the wrong to right;
He has been a coward in the fight.

## A SERIOUS GUN-SHOT WOUND OF THE THIGH WITHOUT HEMORRHAGE.

A. O. STIMPSON, M. D., C. M., Thompson, Pa.

I do not offer this case on account of its being of special interest in a surgical point of view, but on account of its being unique in its occurrence and attended by no serious sequences. On the 11th, day of August 1893, at 5 o'clock P. M., a boy 11 years of age was brought to my office for treatment by his father. While he and several other boys of about his own age, were amusing themselves shooting an old gun, with the ramrod as a projectile (to see how far up in the air the discharge would propel it) the gun was accidentally discharged prematurely and the ramrod was forced through this boy's leg, to one half its length. The leg was transfixed by the ramrod at about 5 inches above the knee joint. The boy said that he was sitting on a stone wall, holding the gun between his knees while loading it, and the gun accidentally slipped downward so that the hammer caught on the edge of a stone with force enough to explode the cap. Strange to say, the ramrod passed through the leg between the first and second layers of muscles without injuring any important blood vessels or nerves or even lacerating the tissue.

I suggested giving the boy chloroform before attempting to extract the ramrod, but as both the boy and his father objected to its employment I got along without it.

After oiling the piece of wood thoroughly with vaseline, with a sudden jerk I pulled the ramrod through his leg in a downward direction, after placing his heel up on a chair. No hemorrhage followed its extraction and after treating the wound with antiseptic dressing and syringing it out daily for three consecutive days with a 10 per cent. solution of carbolic acid, the wound readily closed up leaving no soreness or lameness afterward.

## NASO-AURAL DIPHTHERIA; WITH THE REPORT OF A CASE.

LAURENCE TURNBULL, M. D., Ph. G., Philadelphia, Pa.

Diphtheria. An endemic or epidemic infectious disease of specific origin, attacking the mucous membrane of the nose, pharynx, larynx, and ear, and some other parts of the body.

The ear may become affected by way of the Eustachian tube, and an acute otitis media may develop with perforation of the membrana-tympani, with even necrosis of the mastoid bone. An otitis interna is also sometimes observed.

The question of the identity of the two processes, croup and diphtheria, from a pathological standpoint may be considered to be settled in the affirmative so far as to justify the assertion that true croup, or membraneous laryngitis, may be one form of diphtheria.

The etiology of the disease as to whether it is produced by bacteria is no longer in doubt.

It is of this disease in the ear we write —a case in which the diphtheritic membrane spread to the nasal passages, the Eustachian tubes, and the middle ear. It was accompanied by a gray deposit and a fetid brown discharge. The muscles of the soft palate and ear are frequently affected with paralysis in this disease as a secondary result.

I. N., a girl aged fifteen years, in November, 1891, suffered with deafness—five or six years previous she had suffered a similar attack. She recovered from the attacks and had no earache until about February 26th, 1892, when she complained of most severe pain in the ear. The family physician was called in who diagnosed "an abscess in the ear," but a few days afterwards he thought it had passed away. An attack of diphtheria followed, with abdominal as well as ear

trouble. The girl became extremely ill, and the physician in charge desired consultation with a specialist. She had been removed to Atlantic City, but became worse and the father requested me to go down with him the next day.

He stated that an endemic of diphtheria was caused by some break in the drain, or was brought into the house by one of the children in the spring of 1891. The malignant sore throat had occurred several times in the family, recurring in some persons. The eldest boy, the father and the mother, and also a domestic had follicular sore throat but no membrane. Four of the children had the membrane fully developed, and a one year old baby had a slight attack. All the children, except the daughter who was taken to Atlantic City, recovered without any bad effects.

The treatment mainly consisted in the use of a solution of peroxide of hydrogen diluted with water, made fresh and kept in a cold place, and used frequently. Internal treatment with calomel, one and one-tenth grain every two or four hours. The treatment proved very successful as all the cases recovered. The drainage was completely overhauled, the traps etc., kept flushed with a solution of sulphate of iron, and the whole house was fumigated.

When I visited the young girl at Atlantic City, March 6th, 1892, I found her under the care of Dr. Marvel, who had treated her most judiciously by the free use of tincture of aconite, etc.

She was in bed, her head was twisted to one side, suffering with intense pain, and it was with great difficulty, owing to the deposit of the membrane along the canal, that I could make an examination of the ear, as the auditory meatus was very tender and swollen. When seen there was active congestion of the membrana-tympani with a deposit of fluid.

After free use of a 20 per cent. warm solution of cocaine, I perforated the membrana tympani twice and allowed the fluid in tympanum to escape and then incised the swollen auditory canal.

Temperature during preceding day had ranged from 100° to 104°. When I left in the afternoon she was much relieved and her temperature and pulse were much reduced.

Not hearing from the doctor for some days, I addressed a letter to him on the 8th, and received a reply which I give:

Atlantic City, March 10, 1892.

"Miss N. seems much improved. The temperature range has been only one degree above normal. She seems very bright and full of fun.

"Unless something at present unforeseen develops, I think she is to have a speedy convalescence. The ear has not given her much pain or concern since the operation, though it is yet considerably swollen in the *external meatus*. I am today using the lime water through a cone of absorbent cotton in the ear; there has not been any suppurative discharge—hence I have not thought it worth while to use the bichloride solution.

"Should any change for the worse take place I will notify you. I am indeed greatly pleased with the prompt and palliative change in her condition."

---

The Height of Man.—A French statistician has been studying the average heights of men at different periods of the world's history and has reached some alarming conclusions. The recorded facts extended over nearly three centuries. It is found that in 1610 the average height of men in Europe was nearly 5 feet 6 inches. In 1790 it was 5 feet 6 inches. In 1820 it was 5 feet 5 inches and a fraction. At the present time it is 5 feet $3\frac{3}{4}$ inches. It is easy to deduce from these figures a rate of regular and gradual decline in human stature, and they apply this, working backward and forward, to the past and to the future. By this calculation it is determined that the stature of the first man attained the surprising average of 16 feet 9 inches. The race had already deteriorated in the days of Og, and Goliath was quite a degenerate offspring of the giants. Coming down to later time, we find that at the beginning of our era the average height of man was 9 feet, and in the time of Charlemagne it was 8 feet 8 inches. But the most astonishing result of this man's study comes from the application of the same law of diminution. It is conclusively shown that in 4000 A. D., the height of the average man will be but 15 inches, and in a few thousand years more the end of the world will come, for men will get so short that there will be nothing left of them.—*Buffalo Express.*

# SOCIETY REPORTS.

## PHILADELPHIA COUNTY MEDICAL SOCIETY.

*Meeting of September 27, 1893.*

Dr. T. J. Mays read a paper on

LARGE DOSES OF STRYCHNINE IN THE TREATMENT OF PULMONARY AND CARDIAC DISEASES.

(See page 713).

DISCUSSION.

Dr. Lawrence P. Flick: This is too practical a subject to be permitted to pass without some discussion. There is no drug that has become more popular in recent years than has strychnine just in the class of cases to which Dr. Mays alludes. Whilst we have apparently empirically come to the conclusion that this drug is of very great value in these diseases, I do not know that I have seen a satisfactory explanation of why it is so. There is one peculiar result in the use of strychnine which gives somewhat of a clue to its manner of action. This was not mentioned by Dr. Mays. It is the marked increase of weight that occurs under the use of large doses of strychnine. I do not know of any drug which will produce this effect so rapidly and so satisfactorily. It seems to me to indicate that the real cause of benefit, after all, is possibly the increase of nutrition, and yet why this increase in nutrition from the use of strychnine? It is probable that its effect in stimulating involuntary muscles has a great deal to do with the result. The special action of strychnine is stimulation of involuntary muscles. This is true not only of the muscles of the heart and of the blood-vessels but also of the muscles of the stomach, intestines, etc.

In the treatment of tuberculosis, strychnine is certainly one of the most valuable remedies that we possess. It should be large doses. It, along with many other remedies which go to build up the nervous system and improve the nutrition, are really essential in the treatment of tuberculosis. When we use remedies which build up the nervous system, and with them use the germicides that have lately been introduced, we can obtain very gratifying results in the treatment of this disease which has hitherto been so discouraging. The use of strychnine and other stimulating drugs should be accompanied by the employment of such germicides as have shown themselves to be of value. I have seen recently reports of some excellent results with tuberculin and tuberculidin, and if these reports continue to come as they have, I feel that we can soon approach the treatment of tuberculosis with a great deal more courage than in the past.

Dr. Charles Wirgman: I can give my testimony as to the value of strychnine in asthma. I have a patient suffering with severe asthma, the result of hay fever, taking one-twelfth of a grain four times a day. He is a man of relaxed muscular fiber and rather feeble constitution. He has had these attacks every autumn for some years. I began with one-sixtieth of a grain and increased to one-fortieth, and then to one thirtieth. Observing no toxic symptoms, I increased the dose to one-twentieth and finally to one-twelfth, four times a day, I think with decided benefit to the general nervous tone. I have never observed in this case or in others any accumulative effect of the drug. As far as its influence upon the pulmonary tract is concerned, I have observed no positive action, that is in the sense of an expectorant, but it certainly does increase the general tone so that a patient has more strength to expel the secretion which accumulates. The only symptom that might indicate a toxic action has been a slight amount of spinal irritation, but I have been inclined to attribute this to the semi-recumbent position which he has been compelled to maintain.

Dr. S. Solis-Cohen: There is no question in my mind that large doses of strychnine can in certain cases be well borne for prolonged periods. In hysterical and other forms of aphonia, and in paralysis following diphtheria, I have frequently given as much as one-fifth of a grain three times a day for several days

in succession, having reached this dose by gradual increasement; and I now have under my care a man who has been taking one-tenth of a grain of strychnine three times a day for some two years, and who has at times for short periods taken even larger doses. This is a case of syringomelia with cardiac feebleness. But while I am sure from what Dr. Mays and others have reported, and from my own observations extending over many years, that these doses of strychnine can be well borne and are useful in certain selected cases, I am not one of those who believe that these large doses should be given to every case or to a large number of cases. Both in acute cases and when the drug is to be long continued, I have seen, as a rule, better results from what nowadays would be considered very small doses, namely, about one-sixty-fourth of a grain or one milligramme. The reason for that, I think, is quite clear. In some very interesting researches communicated by Mr. Hodges to the American Physiological Association at the last meeting of the Congress of Physicians and Surgeons at Washington, and in which the effects of exercise and rest upon the ganglion cells of the brains of bees and of sparrows were demonstrated, it was shown that during the periods of activity a certain vacuolation of the gray matter of the nerve-cells was produced; an absolute destruction of the tissue during the physiological process of nervous function. During the period of rest, repair takes place. Strychnine is an agent which above all others stimulates nervous function, and naturally in the process of stimulation of nervous function leads to destruction of nerve tissue. This is, of course, the absolute physical necessity; energy can not only be produced, whether in the body or out of it, by an arrangement of matter—a reduction of existing forms into less complex forms, with liberation of the energy locked up in the complexity of structure. Mr. Hodges also showed some spinal cells from a cat poisoned with strychnine, and called attention to the correspondence between vacuolation in the spinal cells of the cat from strychnine activity and the vacuolation in the brain-cells of bees and sparrows from normal activity; there is no doubt in my mind that the correspondence holds throughout. Strychnine adds nothing to the stores of energy of the patient. Its great usefulness in apparently giving strength to a weak man is due to the fact that it calls upon him for the exercise to the full of such reserve energy as he possesses. It stimulates the nerve-cells to their highest activity, quickly liberating the locked-up energy, and in so stimulating it inevitably uses up a certain amount of nerve tissue. If after this, sufficient rest is allowed, repair takes place, and takes place more quickly because the nutritive processes have been stimulated by the action of the drug. Now, if the amount of activity with concomitant reduction of nerve tissue caused by strychnine can be proportioned to the needs of the patient so nicely that we shall get the maximum of stimulation of the nutritional process and the minimum of expenditure of the patient's nerve tissue, it is evident that that is the proper point at which to stop. Pushing it beyond that, we may cause an unnecessary expenditure of energy and loss of tissue which has to be made up from the food and in other ways. The nicety of adjustment most beneficial is not to be expressed in figures; it differs with the patient and with the disease, and to reach it requires careful observation and good judgment. Still it is something that we should aim at and that every intelligent physician should be able to secure. The fact that we do not kill a patient by large doses of strychnine does not necessarily prove that we have done him good. The fact that a patient is not killed by a surgical operation does not prove that the operation was indicated in that particular case. It may have been or it may not. Dr. Mays has alluded to the tolerance finally produced to large doses of strychnine. In this lies, I think, the patient's safety. The nerve cells become habituated to it, and refuse to respond up to a certain point. It is the small excess beyond this point that is over the amount tolerated, to which the therapeutic effect is due.

In the treatment of acute pneumonia strychnine is unquestionably one of the best agents that we possess, given in proper doses. I have had occasion to observe at the Philadelphia Hospital, in patients side by side, the comparative effect of small and large doses, and while admitting all the difficulties in the way of drawing

conclusions from such comparisons, I am sure that the patients with small doses did at least as well as those who received large doses. I am not afraid to push strychnine up to one-half a grain, if necessary, and when the indication for such dosage exists. In Dr. Mays' cases I have no doubt that large doses were indicated, but in less skilful hands than Dr. Mays' I am sure the routine use of large doses might do harm, not by producing immediate death, but by gradually exhausting the nervous energy of the patient.

In acute cases the best method of administration of strychnine is by means of dosimetric granules. I use the word "dosimetric," not that there is anything magical in the term, but that it indicates the manner in which the granules are prepared. Strychnine arseniate in doses of half a milligramme ($\frac{1}{128}$ grain) can be given and repeated every fifteen minutes or half an hour until the desired physiological or therapeutic effect is produced. The administration can then be stopped, and, as the effect is often prolonged, need not be repeated until the next day. In some cases the nurse can be instructed to administer three or four granules—one granule at a time—at intervals of half an hour, and then none for three or four hours. Sometimes, after a patient has thus been given four granules ( $\frac{1}{30}$ grain), the effect can then be kept up by a single granule twice or three times a day. As I have elsewhere published my views concerning the important place of strychnine in the treatment of affections of the heart, I will not now dilate further upon it.

To repeat what I more particularly desire to contribute to the present discussion, I believe that while strychnine is very useful in all the conditions described by Dr. Mays, the best effect can be obtained by limiting the dose to the smallest quantty that will produce the physiological reaction intended.

Dr. Mays: I do not know that I have much to say in conclusion. The remarks made by Dr. Flick with reference to the influence of strychnine on nutrition are very apropos. The reason that I did not allude to this was because I have discussed this part of the subject in the paper to which I referred. It is quite evident to my mind that Dr. Flick has had a plentiful experience with the use of large doses of strychnine, because, among other things, he notes the influence of this drug upon nutrition. This action is certainly remarkable. I have so often observed this gain in weight that it is a common thing for me to expect the patient to gain in weight if he gets strychnine in ordinarily large doses, such as I have spoken of. I do not know whether Dr. Flick is correct in saying that it acts upon the trophic nerves, However, there is strong evidence for believing that strychnine affects the trophic or nutritive nerves of the body and stimulates them, and in this way improves nutrition. I have seen remarkable gain in weight in experimental cases in which nothing was given but strychnine hypodermatically for a number of days. There was nearly always decided gain in weight in the cases that I have observed. I gave it in large doses.

In regard to the cumulative effect, I do not think that I have any observations in regard to the accumulation of the drug in the system. While I believe that strychnine acts like drugs that do accumulate in the system, such as atropine, digitalis, and strophanthus, yet there is a marked difference between the action of strychnine and the drugs mentioned. Strychnine does not have the profound effect upon the circulation that the other drugs have. We know that the cumulative effect of digitalis is due to the fact that elimination is checked.

I am sorry that I cannot agree with Dr. Cohen in regard to the benefit of small doses in many diseases, although I believe that some diseases are more easily influenced by strychnine than are others. I believe, however, that pulmonic and cardiac diseases, such as were only referred to in my paper, are less easily influenced by strychnine than are many others. It is especially so in asthma, angina pectoris, and the other pulmonary and cardiac diseases to which I have referred, for in them it is perfectly useless to give small doses with the idea of cure. You might as well turn a garden-hose on a Chicago fire as to expect to do much good with small doses in these diseases. I have tried small doses without any benefit.

In regard to the destructive action to which Dr. Cohen has referred, I can hardly

believe that strychnine in ordinary physiological doses can have a destructive influence upon the nervous system, although I can see how a large and poisonous dose could have such influence upon the nervous system. Indeed, we well know that atropine, digitalis, alcohol, and many other drugs in common with strychnine have such a disintegrating effect in toxic doses; but to say that in stimulant cases they have the same or even a similar effect is far from the mark. It seems to me to be a confounding of the physiological with the pathological effects of a drug. Although I administer strychnine in large doses, I always remain within the sphere of its stimulant action. In fact, I fail to conceive how any drug which improves the nutritive state of the body can at the same time have a destructive influence on any tissue, except in so far as it may enhance the physiological waste of the body, which in turn is compensated by an increase in its physiological repair.

## CORRESPONDENCE.

### SOME MEDICAL PHASES OF THE WORLD'S COLUMBIAN EXPOSITION.

To The Editor:—Perhaps the greatest menace against the success of the World's Fair which has just come to a close, was the prospect of cholera which has for two years threatened to invade this country. An epidemic of a disease so deadly and so greatly feared, would have caused financial difficulties which in themselves would have reduced the number of exhibitors and of visitors. Still more would the dread of meeting infection in a crowd have acted to prevent a profitable attendance. As a nation, we must be thankful that the failure of so noble a commemoration has not been added to the disastrous consequences of an epidemic at any time.

The managers of the exposition had before them the sanitary problems of a city of several hundred thousand inhabitants, limited to an area of about a square mile. The water at the dead end of Lake Michigan is appreciably contaminated by the sewage of Chicago, Milwaukee and several lesser towns, with an aggregate population of two millions or more. This water would be especially unwholesome to strangers without even the partial immunity of habit and forced by the exertion of sight-seeing in the heat of summer to drink unusual quantities of fluid. Hygienic need and business acumen lent themselves to each other's service in solving that part of the sanitary problem which had to do with the water supply. At short distances through the grounds and buildings were erected large filters, and no one who drank water could fail to have impressed on his mind the fact that these filters removed all impurities including germs, but left the natural salts and gases in the water. Almost equally ubiquitous were fountains which dispensed mineral water by means of a penny-in-the-slot machine.

Equally imperative with the need for an abundant water supply was the demand for water-closets. This was met by an elaborate sewerage system which, however, did not require the expense of construction of a permanent system. The management has been severely criticised for allowing the closets to be made a means of revenue. Certainly it is not magnanimous thus to take advantage of the calls of nature, but, on the other hand, five cents is not a large sum to pay for the use of a neat toilet room with soap, water and towels, and at least half of the pay closets were associated with free closets, although the latter were made as inconspicuous as possible.

An emergency hospital with a staff of physicians and trained nurses and equipped with an ambulance, was a novel and commendable provision for the comfort and safety of the patrons of the fair.

Equally convenient and, happily, more largely used was the *creche* in the Children's Building, where a hundred babies and little children were daily entertained. A great many foolish parents said they could never think of checking their little darlings as they would a satchel and so lugged them about, a discomfort to themselves and a nuisance to everybody else.

Through the courtesy of the matron, I was allowed to inspect the rooms where the children were cared for. In the first room were cradles, cribs and swings full of babies and two or three were playing in a little enclosure. Most of the children were happy, a few were screaming with hunger owing to the brutality of their mothers who had failed to return hours after the time for nursing. As far as practicable, children who had been weaned were given their accustomed food, condensed milk, infant's food or prepared cow's milk. In many cases it was necessary to modify the unhygienic regimen to which the child had been subjected and to give the parents a little wholesome advice as to the capability of an infant's stomach. The older children were in a separate room from the babies and were fed in a special dining room. The *creche* was visible from the center of the building through huge windows which were crowded with faces, the spectators in front being pushed down by those behind so that their bodies were out of sight. Looking out on this mass of human faces through the bars of the windows I could appreciate the feelings of the caged animals in a menagerie.

Near the children's building was a well appointed drug store in charge of women pharmacists. This was at once an exhibit of women's work and a practical convenience. Under the same roof was a model hospital ward, diet kitchen and operating room. The last contained a glass topped operating table, a galvano-faradic switch-board and quite a complete stock of metal handled instruments, dressings and a steam sterilizer. The room was floored and walled with tiles and was a silent argument in favor of asepsis rather than antisepsis. One corner of the model hospital represented a children's ward, the rest a woman's ward, and a large doll in one of the beds illustrated the dressing for fractured jaw. In a cabinet were a number of dolls dressed in the uniforms of the various training-schools and out-door nursing guilds of Chicago. The blue and white striped seersucker dress and mob cap predominated. The heavily frilled and starched abomination which does duty for a cap in most of the Philadelphia hospitals was not represented. The diet kitcheu was well appointed. Of particular interest was an appliance which made use of resistance to an electrical current to generate heat for cooking. The power was furnished from a lighting wire and a number of heat generators to fit different utensils were connected with a switch-board. These means of cooking are neat, convenient, prompt and—expensive.

In the Transportation Building there was little of medical interest barring doctors' buggies, one or two elaborate hearses and an ambulance car such as was used during the civil war. The last had on each side of the aisle four lengths of berths arranged in three tiers like those in some steamer state-rooms.

In the section devoted to charities and corrections in the Anthropological Building were a number of hospital exhibits. Models of iron beds, cases of bandages and dressings, photographs of nurses, house-staff and attendants, and of rooms; note-books showing the progress of the training schools were among the articles on exhibition. One hospital exhibited a large scrap book filled with blanks of all descriptions. Prescriptions and diet blanks, temperature charts, blanks for reporting deaths, cards for notifying relatives of the serious illness of a patient and passes were among the more useful minority of the blanks. The majority provided for the details in the routine of various departments of the hospital and for a good many emergencies as well. One can scarcely refrain from the suspicion that a hospital with so elaborate a system of red-tape must fail in some of the more essential functions.

Japan, Canada and the United States showed models of disinfecting ovens in use at quarantine stations. All were on the same general principle of a separate boiler-house, with steam conducted in pipes to a large air-tight building of brick and iron into which freight cars could be pushed and the baggage loaded upon them disinfected.

A Michigan sanitarium made an interesting display of gymnasium appliances and of life size and minature models of patients and nurses showing methods of bathing and massage.

Also in the Anthropological Building were exhibits of papier maché models, not only of the human subject but of various animals and plants. One large case was filled with bleached bones showing the

union of fractures. Another case contained a collection of dental specimens and there were interesting remains of bone disease.

One interested in craniology would have found much to engross his attention in the collection of skulls from Peru, the Cliff Dwellers and various American aboriginal tribes.

In the gallery were models and sections of the brain and cord, and apparatus for testing the acuteness of the senses and nerve conduction. Unfortunately, I saw these exhibits only in the evening when they were not in operation, but learned from notices that the tests were conducted on the European plan, ten to twenty cents for the simpler ones, fifty cents for a determination of the psychic power, the last charge including a number of items arranged as on a bill of fare.

Dr. Sternberg had a large number of photomicrographs illuminated by an electric light. Bacteria of various kinds are represented under high magnifying powers. Carmona's bacillus, bacillus acidoformans, Freire's micrococcus, bacillus cumculicida and bacillus racemosus and a number of others besides the usual stock pieces of tuberculosis, pneumonia and gonorrhœa were here shown.

In the gallery of the Manufactures and Liberal Arts Building, were exhibits of dental, medical, surgical, microscopical and veterinary instruments and of drugs. These exhibits simply reproduced the ordinary stock of well supplied dealers, but the fact that they were in charge of intelligent and courteous exhibitors afforded a refreshing contrast to the indifference displayed by the managers of industrial exhibits, who seldom took pains to explain their wares and often left them unattended.

In the agricultural section of the Government Building were preserved specimens and wax models of organs affected with tuberculosis, glanders, hog cholera, Texas fever, contagious pleuro-puemonia and rinderpest. There was a most realistic model of a poultry-yard with chickens dying of gapes, but the most valuable object lesson—on account of possible human infection—was a full sized model of a horse suffering from glanders and farcy. The look of utter wretchedness in the eye, the muco-purulent discharge from the nostril, the hard and suppurating farcy buttons were faithfully shown. It was a clinic of this interesting and rare disease without the danger of infection. The omniverous habits of some cattle were illustrated in a unique collection. Here were hair-balls from stomachs, enough to supply this article of the homeopathic materia medica for all time. A steel rake-tooth about four feet long was said to have been taken from a steer killed at Chicago for beef and, therefore, presumably healthy in spite of this feat in deglutition. A silver dollar, a watch chain, hair-pins, an open jack-knife and quantities of nails and smaller metal articles had been removed from the stomachs of other cattle. In a glass jar were nineteen pounds of stones, varying in size from that of a chestnut to that of an apple and representing the yield of one bovine quarry.

In the division devoted to the treasury department, the U. S. Marine Hospital Service made a creditable exhibit of ward and laboratory appliances.

The Smithsonian Institution, among other things, exhibited many skeletons and models of the internal arrangement of both vertebrate and invertebrate animals, showing the course of evolution. The comparative morphology of the human and the equine skeleton was well shown; as was also the formation of the limb bones, the latter illustrating a number of different quadrupeds, birds, tortoises etc.

Much more might be said in enumeration of the Columbian exhibits which appeal particularly to the consideration of the physician, both in multiplying examples and in giving details. I will close, however, by mentioning a little relic in the Louisiana State Building which suggests a pathetic story of a friendship unbroken by death. This relic was a little silver snuff-box found clasped in the hand of an English army surgeon, who was killed in the battle of New Orleans by a chain-shot, which pinned him to a tree. On the cover of the box was engraved "Captain Arthur Mabbitt to Richard Williams, M. D., 68th Light Infantry," At the doctor's feet lay the body of Capt. Mabbitt who had been killed by a mortar ball.

## EDITORIAL.

### MATERNAL IMPRESSIONS.

"Is it all right, Doctor?" "Is the baby marked"? is almost invariably the second question asked by a mother after delivery—the first being as to sex. The question is the result of the popular belief in the influence of maternal impressions on the fœtus *in utero*.

Physicians are divided on the question though few now accept 'impressions' as the causes of gross physical deformities.

As to the transmission of parental acquired characteristics the subject is more intangible and therefore more interesting. Dr. Andrew Wilson in a recent discussion, quoted in *Public Opinion*, says:

"The battle about heredity, and whether or not characters acquired by the parents can be transmitted to the offspring, proceeds merrily. Scientists are divided over this question. On the one hand, the disciples of Dr. Weismann deny the possibility of such transmission; while their opponents regard the handing on of parental acquired characters as not only a possible but a natural process of the vital economy. Dr. Alfred Russel Wallace, co-worker with Darwin himself, has lately placed on record a very valuable and singularly interesting suggestion regarding the influence on children's character of the parental mind. His contribution (published in *Nature*) tends to show that in the sphere of mental influence of parents on their offspring's character, at least, he is open to admit the validity of the "other side" of the hereditary question. If there is any reality at all in the instances Dr. Wallace records—he says rightly: "They seem to afford grounds for further investigation"—then the influence of the parents in regard to the transmission of ordinary acqui racters cannot surely be put out of court, as some biologists would maintain, as "entirely unsupported by any trustworthy facts."

Dr. Wallace's recital begins with the mention of an instance quoted by George or Andrew Combe in which the character of a child appeared to have been affected by the prenatal studies of the mother. This item becomes interesting in view of the fact that, after a persual of Dr.

Wallace's articles on the question of the inheritance of acquired characters, an Australian lady wrote him on the subject of the parental mind on the unborn offspring. Some of the details given by this correspondent with reference to her own experiences, and to those of another lady, will be read with deep interest by every intelligent person interested in the problems of heredity, and in what may fitly be called the romance of science. The first cases are those of the correspondent's own children. Her first child, a girl, is now twenty-two years of age. She exhibits a special aptitude for sewing, planing and cutting out. Before her birth the mother, passing to reside in a new country, had to plan and sew for herself. The girl has also a strong aptitude for history, which the mother traces to her own study of Froude. The girl's other tastes for art and literature are "distinctly hereditary." A second child, also a daughter, has marked literary tastes, and at six years of age, used to read and enjoy Tennyson's ballads. She is a B. A. of the Sydney University, taking her degree when barely twenty. Before her birth, the mother had interesed herself in literary pursuits. The third child was a boy. Prior to his birth, the current of the family life had changed. The mother had no time for literary studies, or other "studious pursuits," and her occupations were more mechanical in character than at any previous time. The boy "does not inherit the studious tastes of his sisters at all." He is intelligent and persevering, but prefers outdoor work or handicraft to study.

This most intelligent mother next passes to the experience of her friend in support of the idea that parental influences may be thus clearly and directly handed on to the children. This friend, before the birth of her eldest girl, took to the study and practice of ornithology, and did a good deal of bird-stuffing as well. At the age of three years the girl shows an intense desire to study insects and other animals, and later on, takes to dissecting them. This predilection for natural history studies still remains with the girl. The next child, a boy, exhibits a marked liking for medical and surgical studies, and often expresses the wish that he had been "made a surgeon." Prior to his birth, the mother, strangely enough, had nursed a friend suffering from an accident for three months. On the theory of prenatal influences, the nursing and surgical duties of the mother are accountable for the lad's strong bias toward medical studies. The third child, a girl, exhibits artistic tastes of unmistakable nature. She draws well and excels in artistic talent of many kinds." The mother's life, prior to her birth, is described as having been idyllic in character; her parents then "did nothing but fish, catch butterflies and paint them. At least," adds the mother, "my husband painted them after I had caught them, and mixed his colors." There there may be direct heredity here, of course. The fourth child is a "most prudent, economical girl, a splendid housekeeper, and a good cook, and will work till she drops, but has no taste for reading, but seems to gain knowledge by suction." Before the birth of this child, the mother had experienced many trials. Her husband fell ill of fever, and she had to nurse him without help of any kind. The family also sustained losses by floods. "I don't know how I got through that year," adds the mother, but I had no time for reading."

It may be said, and probably will be said, that the mothers are "only wise after the event" when all is said and done. But there is such a singular correspondence of the exact kind between the characters of the respective children and the occupations which engaged the mothers' attention prior to their birth,

that it is impossible to dispose of the cases thus related on the convenient supposition that the facts have been dovetailed into their places and made to fit the mothers' theory. Dr. Wallace remarks that materials must exist in family records and experiences for determining whether there is anything in the idea thus promulgated of parental influence on character."

## TRANSLATIONS.

### CONTRIBUTIONS TO THE STATISTICS OF MAMMARY CARCINOMA.*

The author, Dr. G. Dietrich, has collected from literature 110 cases, and gives a short history of each. Especially considered are 52 cases which occurred between the years 1872 to 1880, in Luck's clinic at Strasburg. Earlier statistics (Winiwater, Henry, etc.) show the disease to occur most frequently between the ages of forty-six to fifty years; the oldest patient was seventy-three, the youngest, thirty-four. 107 cases occurred in women, 3 in men (of these, one died of erysipelas; a second, two and a-half years after the operation, of inflammation of the lungs, and the third, after several months, from a return).

The history following the operation was unknown in 18; 10 died in the hospital.

75 women were married, 17 were widows and 14 were single. About nineteen per cent. had given birth to more than six children; and among 68, there were nineteen per cent. who had nursed more than six children; 12 patients had suffered from mastitis. The shortest time between mastitis and the development of carcinoma was (in 2 patients) three months; the longest period was thirty-eight years.

Trauma was ostensibly the cause in 10 cases; heredity in 6. The right breast was affected in 53, the left in 48 and both breasts in 2 cases.

Pathologically, the scirrhus variety was more often present; less often, the tubular or alveolar forms. Among 95 cases there were 4 in which the skin, or axillary glands seemed to be involved. The axillary glands were involved alone thirteen times; skin seventy-eight times, of which in 20 the process confined itself to skin only, while 58 were complicated with enlarged axillary glands.

Ulceration of the growth occurred eighteen times, adhesions to the pectoralis major twelve times, the first of this series having the cancerous cachexia, leading to the suspicion of internal metastases.

Most of the patients were in good condition for operation, which took place in the majority of cases about seventeen months after the disease had been noticed.

Five patients could not be operated on owing to metastasis, two were operated on although all axillary glands could not be entirely removed and both remained without any return of the disease, respectively eight and five and a half years.

In two cases the axillary vein was doubly ligated and excised. In one case a partial excision of the axillary vein and nerve, also the middle portion of the plexus brachialis became necessary and aside from a transient œdema there was no change of mobility or sensibility.

During the years 1872 to 1880, there were 44 cases with 9 deaths, while in 1880 to 1890, there were 104 cases with a mortality of 8 (7.6 per cent). Three died with erysipelas; 1 from croupus pneumonia and embolism of the lung; 4 from metastasis, *i. e.*, general carcinoma. During the last 9 years there has been no case in which erysipelas formed a complication.

In order to get a more accurate account of the 80 living out of the 95, the author took particular pains to communicate with the patients. He found at the end of September 1891, 28.7 per cent. or 23 living. In 11 the cure lasted 3 years without a return; 2 died 5 years after the operation, not of return but from an intercurrent disease. So that on the

* Translated for THE MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

whole 13, or 16.2 per cent. might be considered definitely cured. Return of the disease was noticed in 45. Of these 13 were treated by operation, 28 in the first and 9 in the second half-year after the operation. Late returns (that is 3 or 4 years) were only noticed in 3 cases. (*Deutsch Zeitschr f. chir*).

# ABSTRACTS.

## PARALYSIS OF THE ARM FOLLOWING THE APPLICATION OF AN ESMARCH'S BANDAGE.

Dr. James Bell related, at a recen meeting of the Montreal Medico-Chirurgical Society, the history of the case, the circumstances being, in his experience, unique. A young woman, twenty years old, admitted to the hospital January 16th, with ankylosed elbow joint. The position was not a very bad one, being a little greater than a right angle. The history of the injury was as follows: On the 6th of last July she fell in a car, and, knocking against the wall, hurt her elbow. At the time she did not pay much attention to it; but after awhile, the joint having become stiff, it was thought necessary to call on a doctor. The latter attempted passive motion, which was partially successful, but the ultimate result was ankylosis in the above position. Excision of the joint was advised, to which she after awhile consented, and the operation was carried out in the ordinary way. It was noticed, after removal from the operating room, that she had no power in any of the fingers, and that even sensation was not normal. Owing to the hand being encased in dressing, no very accurate observation could be made for some days, but it was remarked that the fingers perspired profusely. At the end of the third day after operation, being anxious and unable to explain the paralysis (the operation was done sub-periostal, and he was sure no injury had been done the ulnar nerve, besides injury to the latter would not account for paralysis of all the fingers and muscles of the forearm), the dressing was removed, and the explanation was at once patent. The Esmarch had been applied in the upper portion of the arm, just above the belly of the biceps, and below the prominence of the deltoid, and it had been tied so tightly that the skin was blistered. There was consequently no longer any doubt as to the Esmarch being the cause. The whole operation only occupied forty minutes, so that the band altogether could not have been applied more than half an hour. Upon the discovery of the neuritis she was at once put under the care of Dr. Stewart. Motor paralysis remained absolute for three weeks. On the 21st, day the first sign of movement returned, being a slight motion of the thumb; and after about six weeks' treatment she returned to her home with almost complete power of the arm. Once movement began to appear, it progressed very rapidly. She was able to flex and extend the arm and fingers completely, though not with the full amount of power. There, however, was no motion deficient.

This case is very instructive and very important, in view of the frequency of the application of the Esmarch. It is interesting on account of its rarity. It was the first time he had met with the accident, and considering the number of operations he had seen in the last twenty years, and the recklessness with which the Esmarch had been applied in all sorts and conditions of patients, it seemed to him that this must indeed be a rare complication. It could hardly have occured had the Esmarch been applied in any other part of the body; but it is a lesson well worth bearing in mind.—*Montreal Med. Journal.*

### Common Mistakes of Doctors.

1. To promise a patient that you will cure him.
2. To promise to call at an exact specified time.
3. To promise that the malady will not return.

# THE LIBRARY TABLE.

## BOOK REVIEWS.

*A Text-book of the Theory and Practice of Medicine.* By American Teachers. Edited by William Pepper, M. D. LL. D., Provost and Professor of the Theory and Practice of Medicine in the University of Pennsylvania. In Two Volumes. Illustrated. Volume I. Phila: W. B. Saunders. 1893. [Sold by subscription only. Price per Volume, $5.00]

Among the many books that have been recently written on the Theory and Practice of Medicine we know of none that is likely to meet with as much favor as this one that has been just offered.

Most of us realize that the day has passed when it is possible for any one man, no matter how eminent he may be, to offer to the medical world a work that will either meet the demands of the every day practitioner or equal the collected study, experience and labor of the many who are themselves recognized as specialists in their particular field of work. Such an array of talent has never been associated in an effort of this kind before in America.

That each of these forty-five articles are signed gives much satisfaction.

The care that has been taken in presenting the very latest methods of differential diagnosis of all diseases will be found of the greatest assistance to the general practitioner, as it will not be found necessary to consult any works more especially devoted to the subject.

The chapter on Hygiene by Billings, which includes a full discussion of disinfection, isolation and other principles of preventive medicine, together with the master-piece of Wood on Mental Diseases are deserving of special mention.

The following list of articles completes this volume.

Ephemeral Fever and Simple Continued Fever, Typhoid Fever, Typhus Fever, Relapsing Fever, Cerebro-spinal Fever, Influenza, Dengue, Miliary Fever, Milk Sickness, Mountain Fever; Septicæmia and Pyæmia and Leprosy, by *William Pepper*, M. D., Provost and Professor of the Theory and Practice of Medicine and of Clinical Medicine, University of Pennsylvania. Scarlatina, Measles, Rubiola, Small-pox, Vaccination, Varicella, Mumps, Whooping Cough, Tetanus, Actinomycosis, Anthrax, Hydrophobia, Trichinosis, Glanders, Foot-and-Mouth Disease, by *James T. Whittaker*, M. D., Professor of the Theory and Practice of Medicine, Medical College of Ohio, Cincinnatti. Acute Miliary Tuberculosis, Scrofula, Syphilis, Diphtheria, Erysipelas, Malarial Fevers, Cholera, Yellow Fever, by *W. Gilman Thompon*, M. D. Professor of Physiology in the Medical Department of the University of the City of New York. General Symptomatology of Diseases of the Nervous System, Mental Diseases, Functional Nervous Diseases, Syphilis of the Nervous System, Organic Diseases of the Spinal Cord and its Membranes, by *Horatio C. Wood*, M. D., Clinical Professor of Nervous Diseases, University of Pennsylvania. Organic Diseases of the Brain, Diseases of the Nerves, Diseases of the Muscles, Vaso-Motor and Trophic Disorders, by *William Osler*, M. D., Professor of Practice of Medicine, John Hopkins University, Baltimore, Md.

---

*The Health Resorts of Europe.* By Thomas Linn, M. D. London: Henry Kingston, 82 High Holbone W. C.

This is a hand-book of 300 pages, written by a distinguished American graduate in medicine, who is also doctor of medicine of the faculty of Paris. Dr. Linn has had a large experience in the health resorts of Europe, their mineral springs, of the climatic changes of these regions, he having been the physician of the famous bathing establishment at "Aix Les Bains and Marlioz" for a number of years.

The book is very much superior to the usual guide books, as these are written by non-professional people, and while they give correct information, they contain errors that make them useless from a medical point of view. All the resorts are written up in this work, while special attention is paid to the sanitation of each station, and its general hygiene.

We feel sure the book will be found useful both to the public, and to our professional brethren, who may not have had opportunity of making personal observations of these European resorts.

Dr. Linn quotes an interesting table lately drawn up, showing the cost of living in different countries. According to the same, it would appear that outside the expensive quarters in London, England is the most reasonable, next comes Switzerland, 4 per cent dearer; then Germany, 10 per cent. higher; then France, 15 per cent.; Italy, 20; and the United States (as represented by Pennsylvania); 24 per cent. higher than England.

The preface to the volume is from the pen of A. C. Samson, M. D., F. R. C. P., of London, England, a well known physician of that city, who very properly emphasizes the importance of invalids consulting their own medical adviser before going abroad in search of health. With the aid of this useful volume physicians can post themselves, and be able to give the proper advice to their patients.

---

*Clinical Lectures or Abdominal Hernia.* Wm. H. Bennett, F. R. C. S. London and New York: Longmans, Green & Co.

Review of Dr. Wm. H. Bennett's lectures on hernia are well worthy of the consideration of the medical profession. They cover the ground in a most thorough manner and indicate a thorough investigation of the subject by a surgeon who has derived his exper-

ience through service at the operating table. This work should be in the hands of the entire medical profession. Any one who is doing special work in abdominal surgery should read it and appropriate its many good points.

---

*Cosmopolitan for November.*

A magazine is usually satisfied with one strong feature for the month. *The Cosmopolitan*, however, presents for November no less than five very unusual ones. William Dean Howells gives the first of the letters of the traveller, who has been visiting this country, from Altruria. We have read Mr. Howells' impressions of the Altrurian; but in this first letter we have the Altrurians' impressions of New York, with some comments upon the government and society, calculated to awaken the most conservative minds. The second feature of *The Cosmopolitan* is the portion of the magazine given up to color work, no less than ten superb color illustrations being presented for the first time in magazine history, accompanying an article by Mrs. Roger A. Pryor on "Changes in Women's Costumes." The third feature is "American Notes," by Walter Besant, who was recently in America and is doing the United States for *The Cosmopolitan a la* Dickens. The fourth feature is by General Badeau on "The Forms of Invitation Used by the English Nobility." The article is illustrated by the fac simile of cards to the Queen's drawing-room, to dinner at the Princess of Wales, and to many leading houses of England. Finally, we have a new and very curious story by Mark Twain, called "The Esquimau Maiden's Romance." It is in his happiest vein and is illustrated by Dan Beard. The November number presents the work of many artists, among whom are: C. S. Reinhart, Otto Guillonnet, J. H. Harper, G. Hudson, Frank von Lenbach, George Wharton Edwards, F. Schuyler Matthews, Dan Beard, W. L. Sontag, Jr., F. G. Atwood, C. Hirschberg, J. Habert-Dys, August Franzen, Louis J. Read, J. N. Hutchins and Hamilton Gibson.

---

*System of Diseases of the Ear Nose and Throat.* Edited by Charles H. Burnett, A. M. M. D. In Two Volumes. Vol. 1, 8vo., pp 789. Illustrated Philadelphia: J. B. Lippincott Co. 1893. Price, Cloth, $6.00; Full Sheep, $7.00; Half Russia $7.50.

We are very glad to welcome this system of Diseases of the Ear, Nose, and Throat.

The entire system is comprised in two volumes, the first volume being devoted to the ear, the nose, and the naso-pharynx, while the second volume is occupied with the consideration of the diseases of the pharynx and of the larynx.

Men of acknowledged skill as specialists in this field of work, both in America and Europe, have labored together to complete this work.

The opening chapter on Anatomy and Physiology of the Ear and tests of Hearing by William Satier Bryant, A. M., M. D., is an exhaustive article and well worthy of a careful study; for on a correct knowledge of the structure very often depends the basis of sound, careful and well directed treatment.

The chapter on chronic Purulent Otitis Media by Charles H. Burnett says "Every endeavor should be made to check a chronic purulent discharge from the ear. There should be no fear to do this as promptly as possible, for so long as a chronic purulent discharge comes from an ear, the patient's life and hearing are in danger;" again he says, "that whenever an acute purulent ostitis media is properly treated it never becomes chronic"; again "no case of acute purulent inflammation will become chronic, *no matter what its cause*, if properly treated at the outset."

Possibly mention should be made in passing, of the articles on Foreign Bodies and Osseous growths in the External Auditory Canal, including neoplastic closure by Sir William Bartlett Dalby; Acute Rhinitis by Dr. F. H. Bosworth, and Diseases of the Accessory Sinuses of the Nose by Dr. Joseph Bryan.

The book contains an unusual number of illustrations, some of them colored. The publishers are deserving of much credit for the quality of the paper and the good press work exhibited.

---

*Diseases of the Rectum and Anus: Their Pathology, Diagnosis and Treatment.* By Charles B. Kelsey, A. M., M. D. Fourth Edition, revised and enlarged: With two chromo-lithographs and one hundred and sixty-two illustrations. Published by William Wood & Co., New York.

That this well known text-book has reached its fourth edition certainly demonstrates its value and the appreciation in which it is held by the student and practitioner.

Before allowing this edition to come before the profession, there has been incorporated in it and whatever of value has been added to our fund of knowledge by the labors of others in the same line of work. Dr. Kelsey certainly deserves much praise for the creditable and masterly manner in which he has performed his task.

The book contains eighteen chapters. The chapter on "Fistula" is well worth the cost of the work. "Hemorrhoids" is another good chapter, fifty-three pages are devoted to their consideration. Prolapse and invagination are studied as four distinct varieties. 1. Prolapse of the mucous membrane alone. 2. Prolapse of all the coats of the rectum, including, when the disease is of sufficient extent, the peritoneum. 3. Prolapse of the upper part of the rectum into the lower, or invagination. 4. Invagination in the continuity of the intestine.

Under the head of non-malignant growths of the rectum and anus are included polypus, vegetations, condylomata, benign fungus, fibromata, lipomata, enchondromata, and the various forms of cysts. The many different varieties of non-malignant ulcers which are met with at the anus and within the rectum, are classified from the standpoint of etiology; into the following groups: 1. Traumautic. 2. Catarrhal. 3. Tubercular. 4. Scrofulous. 5. Dysenteric. 6. Venereal.

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

THE NEW YORK JOURNAL OF GYNECOLOGY AND OBSTETRICS

for October.

Dr. John N. Upshur contributes an article on

**Reflex Bladder Troubles.**

The author considers the most common cause of vesical troubles to be some lesion of the uterus, affecting the bladder through reflex sympathy, although he fully recognizes other agents, such as urethral caruncle, seat worms, etc. Sometimes great vesical distress will be found in very young girls even at the age of three or four years, due to acid urine, caused by eating too many sweets. This form of trouble is not always confined to children, as a too acid urine, or one containing an excess of solid constituents, especially the latter, may give rise to vesical distress, most intense in character and attended by pain in the back and down the thighs, weight in the lower part of the abdomen, with frequent calls to empty the bladder, and may even give rise to a suspicion of uterine disease. The existence of fissure or hemorrhoids may sometimes cause great vesical distress, but as soon as these affections are discovered as the cause, the indication for relief is very plain. Pressure from the gravid womb in the latter stages of pregnancy when many children have been borne, is a common cause of vesical distress. Another class of cases is found in which both centric and excentric influences are at work, as for example, the woman who for some reason retains her water too long after the call to void it, causing over-distention of the bladder, which in time causes retro-misplacement of the womb, and results in permanent debility of the sphincter and detrusor muscles of the bladder, with inability to retain urine for a long time. The calls to empty the bladder are frequent, unsatisfactory and incomplete, the residual urine becomes ammoniacal and acts as a local irritant; secondarily there comes a reflex influence from the misplaced womb, first because it is dragging on the bladder, and secondly because, being misplaced, all of the ills due to malposition are liable to occur, and many do coincidently exist, and thus the reflected influence from a diseased womb adds to the trouble of a debilitated bladder.

In regard to the treatment, the author advocates the use of some one of the alkaline diuretics in case the urine be found to be too acid. He strongly condemns the use of harsh injections into the bladder, especially when used empyrically, and particularly when the agent is nitrate of silver. The treatment is too painful and is liable to aggravate the trouble. The cause of the trouble must be located. The author has found that when gastric derangement was the cause, resulting in an acid, offensive urine, with pain in voiding, the benzoate of ammonia, gr. xv, every two, four or six hours, will sometimes afford very prompt relief or resort may be had to some other agent which will so modify the gastric condition as to produce a bland and sterile urine. When all else fails, resort may be had to drainage either by a self-retaining catheter, if its presence in the bladder can be borne, or by paralyzing temporarily the vesical neck by such extreme stretching as to permit constant dribbling, the person being for the time protected by wearing a nicely adjusted urinal; or by an artificial vesico-vaginal fistula.

The other papers in this month's issue are: "Congenital Dilatation of the Urethra," by W. H. Baker; and "The nature of Shock," by Dr. Eugene Boise. [As this paper is practically the same as one published by the author in The Annals of Gynecology and Pædiatry for October, it will be reviewed in connection with that journal.—ED.]

THE ANNALS OF GYNECOLOGY AND PÆDIATRY

for October.

Dr. Eugene Boise contributes an article on

**The After-treatment of Cœliotomy Cases with Special Reference to Shock and Septic Peritonitis.**

The three post-operative conditions, which, by reason of their serious nature, call for prompt and intelligent action on the part of the surgeon are secondary hemorrhage, shock and septic peritonitis. In regard to secondary hemorrhage, the treatment should be mainly preventive, and consists of careful, certain securing of all possible sources of hemorrhage at the time of operation. But, as an additional preventive measure, and one whose importance is sometimes under-estimated, continuous watchful care must be exercised to prevent sudden movements on the part of the patient, or turning or tossing during the first few hours following the operation. If hemorrhage does occur, the only remedy is to re-open the wound and re-tie the bleeding artery. If the patient's condition will not allow of this, the author suggests to secure the vessel by clamps, close the wound as securely as circumstances will admit and wait for reaction. The author suggests that the transfusion of one or two pints of normal salt solution before opening the wound will greatly improve the patient's chances of recovery in desperate cases.

Shock he regards as a severe irritation of the entire sympathetic system and in no sense a paresis. Such, at least, is the condition

primarily though he admits that after a variable period the entire condition may change without any perceptible change in the symptoms. All muscular tissue tires after a period of unusual activity. This is equally true of involuntary as of voluntary muscles. And although the nerve impulse continues irritant in nature, the heart muscle is weakened, and cannot contract with normal vigor. The arterial spasm is at the same time violent. The frequency of the heart beat may continue the same, but the size of the blood current will not be increased.

The conditions which exist during and after a cœliotomy, which is productive of shock, certainly would seem to be such as would give rise to an impulse of irritation rather than of paresis, for instance—the compression of the nerve fibres by the ligature, the severe manipulation of the intestines, the forcible separation of adhesions, whereby the peritoneum always suffers more or less violence—all are extremely irritant in nature.

In regard to the treatment of shock; when first seen, the patient's head should be lowered, and nitrite of amyl freely administered, with possibly hypodermics of nitroglycerine. The surface of the body should be kept as dry as possible to prevent unnecessary chilling by evaporation. As the author considers the condition to be one of extreme irritation, he advises directly sedative remedies and especially cœdeine, of which he administers at least one grain hypodermically as soon as the patient is placed in bed, and repeats the injection in one two or three hours if necessary. He answer the objections that have been raised against the use of opium by saying that there are no symptoms to be masked by its use thus early and that so far from the checking of the secretions and the stopping of the peristaltic movements of the intestines being deleterious he ragards it as just the reverse, since in shock the prespiration is excessive and the peristaltic movements painful and irregular. Hot water used freely by injection into the colon or transfusion into a vein, he considers a remedy of great importance in the treatment of shock. The indications for its use are to allay the great thirst which follows an abdominal section and to refill the blood vessels. If the shock extends into the second period,, where cardiac and arterial spasm are replaced by cardiac weakness, by reason of "muscle tire," he advises the free hypodermic use of strychnia, digitatis and other cardiac stimulants.

In the post-operative treatment of threatening sepsis (or peritonitis) he advises free catharsis by means of the magnesia salts or calomel, if the stomach will not tolerate the magnesia. In ordinary cases where there has not been much irritation of the abdominal or pelvic contents, there will be no difficulty in producing catharsis after thirty-six or forty eight-hours. But in those cases where the dissection of tumors etc., has been difficult and prolonged, where there has been severe manipulatian of the intestine,, with perhaps direct and intense irritation of ganglia and plexuses, there is generally a more or less severe irritation of the intestines. This manifests itself by paroxysmal pains, often extremely severe, which are caused by spasmodic and irregular peristalsis. Here there is always over-stimulation of the motor nerves of the intestines and fuel is only added to the fire by the exhibition of stimulating cathartics. The indication is to severely abstain from everything that tends to stimulate peristalsis until, by the subsidence of the pain or the escape of the flatus, we can perceive that normal peristalsis is re-established, and the conditions are favorable for gentle unirritating catharsis. If the abnormal activity of the intestines be severe or prolonged, the author advises the early administration of a free dose of codeine; which relieves the pain, quiets the patient and relaxes intestinal spasm, and allows the re-establishment of normal painless peristalsis.

The effusion of liquid into the peritoneal cavity also hinders catharsis by depleting the intestinal blood-vesssls. Much will be gained, the author thinks, by waiting till this flow is checked and the blood vessels have been given time to replenish themselves from the fluids in the tissues. It will be of benefit to precede the administration of salines by a rectal iujection through the long tube of at least a pint of hot water, which will be rapidly absorbed by the vessels. Then the introduction of a concentrated solution of sulphate of magnesia will easily establish the flow of fluid toward the intestinal canal and promote the rapid absorption of the fluid present is the peritoneal cavity. Thus good intestinal drainage is established.

If septic peritonitis is fairly established the forlorn hope is to re-open the cavity, thoroughly flush and a establish free complete drainage, both through the wound and the intestinal canal. Intestinal drainage may be difficult of production from the over—distension of the muscular coat by imprisoned gases, To remedy this and thus allow the muscular fibres to regain tone, a free incision into the intestine with perhaps establishment of a temporary artificial anus, will be good surgery.

Dr. Andrew F. Currier in an article on the

**Intra-uterine Tampon**

gives the indications for its use and the materials of which it should be made. His preference is for antiseptic gauze, inserted in strips an inch wide and eighteen inches long. He advocates the use of the tampon for the induction of labor, in a prolonged first stage of labor due to rigidity of the cervix and in post-partum floodings. In the unimpregnated uterus he advocates its use after curettage, to check hemorrhage and for the relief of the painful and profuse menstruation in young girls. Its use is also advised in endometritis and in place of stems in the treatment of stenosis. He considers it applicable in a limited extent in cases of tubal disease in order to drain ofi the accumulated fluid. In regard to the contra-indications for its use, he says "The tampon

may be so modified in as to quantity, firmness and duration of retention that I am unable to conceive of the impropriety of its use in any case in which intra-uterine treatment is admissible."

Dr. A. H. McFarland discusses the

**Relations of Operative Gynecology to Insanity.**

His conclusions are as follows:

(1) Gynecological operations are more likely than any other surgical procedures to disturb the mind.

(2) Hereditary antecedents of the patients should always be determined.

(3) In insane patients operations should be performed only when the physical condition endangers or renders life insupportable,

(4) Patients, precedent to the operation, should be in a calm frame of mind—hence, moral treatment of the patient previous to operating is the best prophylaxis.

(5) Inherited and acquired insane constitution is the fundamental factor in most cases of insanity. This conclusion does not, however, justify us in ignoring physical discases immediately preceding or associated with insanity.

(6) Healthy genital organs do not give rise to reflex symptoms, consequently caution should be exercised in operating for the relief of insanity.

(7) Operations may be satisfactory in properly selected cases.

Dr. Joseph Tabor Johnson considers the subject of

**Ectopic Pregnancy in the Later Months.**

The chief object of the paper is to recommend the removal of an extra-uterine fœtus in all cases as soon as the diagnosis is made, and the gestation sac or placenta whenever possible, whether it be the second, fourth, seventh or ninth month. If the child can be saved, victory is still greater. The dangers of hemorrhage increase with the development of the placenta and in some cases the author believes it may be wise to leave the placenta undisturbed, with its tied cord protruding from the lower end of the wound, and subsequently remove it after its circulation has dried up; or if no sepsis occurs, it may be left to come away piecemeal, or become encysted and absorbed.

The author reports two cases operated on after the death of the fœtus, with one maternal death.

Dr. A. Vanderveer discusses the subject of

**Drainage of Ovarian Cysts Where the Adhesions are Such that it is Impossible to Remove the Sac by Cœliotomy.**

The author reports seven cases where the proceeding was resorted to. In carrying out drainage in these cases the patient should be put in the care only of a conscientious, judicious nurse. A glass draingae tube should be employed and made to reach to the deeper portion of the cyst, and whatever remains of the cyst walls and adhesions. A rubber drainage tube cannot be relied upon at first. Gauze packing is preferable to the latter.

The author advocates the procedure only in those cases in which it is impossible to make a complete operation, and in such desperate cases where the patient is likely to be carried beyond the point of possible recovery, and to die by shock, because of the too severe tax made upon the weakened vitality of the system.

Dr. J. M. Keating contributes a paper on the "Mechanical Action of the Intestines on the Uterus." The author believes that many of the displacements found in the growing uterus are due to the intestinal dyspepsias of the child, which are the result of improper diet. The article is illustrated by two half-tone plates from photographs.

Dr. Augustus P. Clark contributes an article "On the Value of Certain Methods of Surgical Treatment for Chronic Procidentia Uteri." The various operations for the relief of this condition are carefully considered and the author advocates vaginal hysterectomy in cases of intractable prolapse.

Dr. Charles W. Rook discusses "Contraction of the Cervix Uteri Upon the Neck of the Fœtus, a Source of Danger to the Latter, and a Frequent Cause of the Prolongation of the Second stage of Labor." The author reports four cases of the accident. (In two of the cases reported, ergot had been given and it seems possible that the accident could be attributed to the use of the drug previous to delivery.—Ed).

Dr. H. McHatton contributes a paper enritled "Four Women who Refused Oophorectomy, and their Subsequent Histories." The patients are all living in the best of health in spite of the fact that each was advised to undergo an operation by well-known specialists. The author condemns indiscriminate operating.

In the Department of Pædiatry, Dr. William P. Munn contributes an article entitled

**Diphtheria Associated with Scarlatina; A Clinical Study.**

The points that he considers proven by an analysis of cases are:

(1) The membranous sore throat which so frequently occurs associated with scarlatina is true diphtheria.

(2) Association with scarlatina increases the fatality of diphtheria.

(3) Laryngeal and nasal involvement are more frequent with the associated diseases than with uncomplicated diphtheria.

(4) Paralysis does occur as a sequel.

(5) Both scarlatina and so-called scarlatinal diphththeria may communicate diphtheria without any scarlatinal accompaniment, both to those who have had, and to those who have not had, scarlatina previously.

The remaining papers in this issue are: "Intra-uterine Asphyxia, with Report of Three Cases," by Dr. George F. Hulbert; and the report of a "Fibroid Tumor Complicating Delivery," by Dr. T. J. Crofford. A review of this paper has already appeared in the issue of The Medical and Surgical Reporter for October 14th, 1893, page 616.

## MEDICINE.

### Influ nce of Horziontal and Vertical Positions on the Cerebral Functions.

Sicard de Plauzoles (*Ann. de Pysch.*, 1893) lays stress on the function of the blood in maintaining the activity of the brain. A continuous circulation of the blood is a necessary condition, he says, for the regular action of the cerebral cells. Suspend momentarily the circulation in the encephalon and the phenomena of nervous activity are interrupted. The circulation of the blood is affected by the different positions of the body, the horizontal position accelerating and the upright inhibiting it. The carotid and vertebral arteries at the base of the brain anastomose in the hexagon of Willis, and in an erect position this latter rests on them, pressing them down upon the base of the skull, thus diminishing the flow of blood over the cortex. The brain-mass, being smaller than its bony covering, is capable of slight changes of position, according to the posture of the individual. Where stretched out horizontally, the cerebral substance loses its contact with the frontal wall, and in standing the upper portion rests on the lower part of the brain.

When, after lying down for some time, one suddenly rises, the brain passes from a congested to a relatively anæmic state and vertigo results. The modifications of the brain circulation, which cause vertigo, can be produced in two opposite ways—by congestion and anæmia.

Delirium may be due to these opposed conditions, and, indeed, all phenomena of cerebral origin—as convulsions, insomnia, etc.—may be caused by two contrary circulatory conditions.

Congested vertigo increases in a declined position of the head; anæmical vertigo in the erect position. Further, vertigo is often caused by sudden changes of attitude.

Normally, man passes a certain number of hours in the vertical position and in the horizontal position, and in the case of a healthy man it is difficult to perceive any very appreciable modifications of the play of thought following these changes of the cerebral position; but, in the case of persons mentally diseased, S. has found marked modifications, corresponding to these two periods.

One patient suffered for several weeks with insomnia. Before rising he was delirious, had continued feelings of faintness, and thought he was about to die, the violence of his sensations being lightened relatively to the amount of sleep he had obtained during the night. The temple pulse was more violent than when erect, the two not acting simultaneously, and the left more feeble than the right. During the day the patient improved, but in the afternoon, on extending himself in a hammock, the delirious symptoms returned.

Other cases are also cited. He sums up his statements thus:

Mental disturbance is greatest (1.) after a long horizontal condition—in the morning for example; (2) after a long vertical condition, in the evening, the intermediate hours being the least disturbed.—*Jour. of Nerv. and Ment. Dis.*

## THERAPEUTICS.

### Esencia De Calisaya.

Since this preparation was first put upon the market by it has grown rapidly in favor as a tonic, stomachic, and to a lesser extent as an antiperiodic. There are few cases in the convalescent stage to which it is not applicable, especially if anorexia, weakness, and physical and mental depression are to be overcome.

It is a well-known fact, moreover, that the combined alkaloids of the cinchona bark are much more effective as a tonic than any one of the same taken singly. They are to be preferred in many instances as an antiperiodic particularly where the periodicity of the attack has been in some degree mitigated. It is for this reason that the East India Government now provides its officials with what is termed "Cinchona Febrifuge"—which is but a combination of cinchona alkaloids—in preference to quinine. While cases are encountered where quinine seems practically indispensable, there are few that will not yield, and more satisfactory, to a combination of cinchona alkaloids if persisted in.—Esencia de Calisaya and Cinchona Febrifuge are practically identical, save that the former is a fluid medicament, the latter a powder.

Esencia de Calisaya has been employed and highly recommended as a tonic in neurasthenia and other forms of disease that are the result of, or connected with, general physical and mental depression. *Apropos* of this, Dr. Wyatt Wingrave, Surgeon at the London Throat and Ear Hospital remarks:

"I have great pleasure in expressing my appreciation of Esencia de Calisaya. It is an ideal 'Pick-me-up' and general tonic. It is slightly stimulant to the gastric mucous membrane, and is particularly useful in atonic dyspepsia. *In the alcohol habit, it satisfactorily neutralizes the craving for spirits*, and will be found of great service in treating this distressing disease."

| " **C. B. Brigham, R. B. Cole, Levi C. Lane, J. Rosenstirn,** | *SAN FRANCISCO* |

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it, not only for its purity, but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M. D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

**NO OPENERS REQUIRED.** In using G. H. Mumm & Co.'s Extra Dry in sick rooms and families.

**CHAMPAGNE IMPORTATIONS.** Custom House statistics of 1892 show G. H. Mumm's Extra Dry to be 75,880 cases, being more than one fifth of the entire champagne importations and over 9,000 cases more than of any other brand. It is noted for its excellence, purity and natural dryness.

G. H. Mumm & Co.'s Extra Dry of the excellent 1889 vintage is attracting great attention for its natural dryness, purity and quality.

## ORIGINAL ARTICLES.

### THE GREAT VALUE OF A CLOSE OBSERVATION OF OTHER MEN'S WORK.*

W. H. LINK, A. M., M. D., Petersburgh, Indiana.

It is much to be regretted that most of our American surgeons are content to play a game of surgical solitaire. Absorbed in the magnitude of their own work, and busied with the perplexities of daily experience they forget the existence of others laboring in the same field and too frequently ignore the work of both friends and rivals.

True, the meetings of societies are attended. At these meetings papers are read and the various questions are discussed alike with intelligence and enthusiasm. All this may strengthen and brighten the intellectual powers generally; may freshen the memory, increase the vocabulary and help to outline and identify accepted and well settled doctrines; indicate, enlarge, modify, or limit the proper field for surgical effort and investigation. While this may serve to keep up the enthusiasm without which no great science advances, it adds but little to the skill or success of each individual operator. No one perfects his technique, discards his methods, improves his materials, or succeeds in his results, merely by participating in the discussion of abstractions or listening to the reading of highly ornate reports which so often constitute the intellectual pabulum set before the fellows of our great medical associations at their stated annual meetings.

Each operator, be his experience great or small, has qualities both negative and positive. No one is perfect; neither is any one devoid of ideas that may be adopted or assimilated to advantage.

All successful operators have traits peculiar to themselves; attributes that stamp their work as original.

It is by the tireless energy of originality and the endless application of original methods to both the expected and the unexpected in surgery, that has thus far pushed our work and its underlying science toward perfection. It is these same elements that are to explore new fields and score new triumphs along paths long since pressed by the feet of genius, learning and skill.

To be trained in the routine of what has become already a common heritage, to only imitate or reproduce the achievements of the great names in surgical history is one of the possibilities that belongs to mediocrity.

As the stream of knowledge rises higher and higher, as the fountains grow fuller and fuller, mediocrity will be almost a universal fate: and, while the general professional level may be a very high one, yet a general level there will be and few, indeed, will be the upturned faces that float above the surface of the common sea.

As our science becomes more nearly a closed book less will be left for genius to

* Read at the 19th annual meeting of the Mississippi Valley Medical Association.

accomplish. Unsolved problems becoming fewer and fewer, the great body of fixed knowledge will furnish a field great and broad enough to satisfy the most exalted intellect. The multiplied achievements of the past, will serve for both study and precedent. The infinitesimal accretions piled up by countless workers who have had their day will become the property of the few who may, at any one time, occupy the future stage of action.

By close and frequent observation defects in technique and improper application of surgical measures may be noted, and, having been recognized these may be avoided.

The greatest commanders have blundered. The greatest poets have limped in their measures. Homer himself did sometimes nod. Even the divine Shakespeare could not sustain an even flight. Our greatest operators may be pardoned if not free from error; but their faults, when seen, should become doubly instructive to the observer, who should set them down on his chart that he may deny himself a like experience. All that is good in their work should be copied or carefully studied until originality working patiently and conscientiously can replace it with what is better.

Without just, intelligent, and searching criticism there can be neither advances into strange territory nor a correct appreciation of what has become already common property. Criticism, except of the carping and most superficial character, cannot exist without close, accurate, and abundant observation.

Unless we pause long enough to study carefully and thoroughly what has been given us to have and to hold, we shall be found ignorant of what lies beyond, or what difficulties have been made the easiest of problems.

By observation, honesty in reporting is encouraged. If one's work is to be carefully scanned by intelligent visitors, only statements will be put forth that are sustained by the every day results as seen at the operating table and the bedside. That man's statements alone are to be doubted who makes marvelous claims of success, who publishes great series of wonderful operations and at the same time closes the door upon visitors. But, because one operator on his own statement, breaks the record, no one who has not observed his work is justified in decrying statistics merely because they throw his own experience into the shade.

By observation men are inspired to do their best, and the daily practice of the nicest refinements of technique becomes automatic as constant repetition leads to ease of execution and grace of action.

In the observer, modest self-confidence is promoted, while egotism is rebuked if not abashed.

He who is absorbed in himself, and charmed into a state of self-sufficiency by his flatterers, needs very much to see what others are doing; for it is possible to become so much in love with self that further advance is out of the question till a professional looking-glass is broken and vision penetrate the field beyond. When an operator reaches the point that you can hear nothing but "my instrument," "my modification," "my method," it is a good time for him to look about and see what his friends are doing.

When the spirit of observation and comparison is abroad, experience throws open the door to the honest investigator, and the knowledge and skill that have accrued for the benefit of the suffering are carried away in ever widening circles, till every shore of surgical thought and every island of gynæcological theory are touched by a common ocean.

Equals may profit by watching work illuminated by the experience and skill of each other. No two men think, observe or act identically. No two parallel each other at all points. One is often the complement of the other. Where one is strength the other is weakness. By mutual observation inequalities may become less manifest, and the weak points of the one may be dropped for the strong ones of the other.

A closer and more frequent observation of the work of American surgeons by one-another would redound more to the honor of American surgery and lessen the colossal egotism of foreign operators who fancy that because we pour such hordes of Dr. students and observers into their clinics, we must have no teachers at home.

There is no field in which object lesson teaching is so effective, so fruitful of valuable practical results as in gynæcological surgery. The observer may not always know whether the operation he witnesses

carries the patient on to recovery or the contrary; but, if a close observer, he is improving his own surgical judgement. He is studying, rejecting, or adopting methods and aphorisms as they impress his intelligence or his reason approves. He gives each a place in his memory according to its measure of value.

There must be approved technique, superior skill, aptness and deftness both mental and manual to secure the best results; and results furnish the only satisfactory logic in support of methods. That surgery is the most ideal which gives the highest per cent. of recoveries. It is of but little interest to the patient whether she is drained or not drained, so she gets well and with the least trouble or annoyance. So that hernia does not follow, all questions of closing are the merest tweedle-dum and tweedle-dee to her; these things are of vital importance to the observer who settles them and a thousand one other questions for himself and in the interest of those who trust in his conscience and his skill.

The quick, interested observer finds little or no difficulty in detecting the weak or strong points of a procedure and he gains much by contrasting the methods of different operators as he has witnessed their application.

A surgical triumph or a surgical disaster may be equally instructive in the light of a method by which the one is duplicated and the other avoided. In the presence of the most appaling surgical accident the resources of an operator may display themselves in a succession of victories that leave a most lasting impression upon those who are simply studying the work.

The intelligence too dense to be penetrated by the lessons set before his eyes at the operating tables of the great masters in the profession, ought to be presented with a cap and bells and assigned to a chair in some little one-horse poly-clinic in an obscure town where everything exists in great variety and marked abundance—except students and clinical material.

Because there is so little mutual observation the really brilliant and original man is often unappreciated and misunderstood. His very originality and success often expose him to the accusation of being a surgical heretic, a sacreligious iconoclast who hampers himself by no obsolete rules; but, who, like Napoleon, wins his battles on lines of his own choosing and according to principles evolved by his own genius and justified only by the inexorable logic of success.

These shafts of calumny, these mental brick-bats are hurled at the heads of these who rise above the dead level of mediocrity, by those who find it easier to imitate than to analyze and whose minds catch and hold mostly the rubbish of the past. To be maligned, abused and robbed of a just fame is one of the rewards that often befalls the benefactors of the human race and the masters in medicine are no exception to a rule that has embittered the lives of some of the greatest.

Mutual observation among those who teach both by their writings and their clinical work, would do away with provincialism and create a common feeling of respect and confidence. New York would not look askance at the radicalism of Philadelphia; Philadelphia would no longer turn up her nose at New York's poke-easy conservatism: Indianapolis would not then assert that Birmingham departs abruptly from the truth. Chicago, while her gynecologists and electricians were beating their swords into plowshares and their knives into pruning hooks and learning war no more, might be found a medical center equal to any, while much nearer to the student than Paris or Berlin.

Though the mutual observation of teachers and leaders of surgical work in our large medical centers would soften asperities, increase mutual respect and confidence, lessen back-biting, destroy envy and jealousy, diffuse correct methods and doctrines and everlastingly demolish that disgusting toadyism which loves to abase itself before foreign shrines—a consummation devoutly to be wished by all who have at heart the honor and glory of America aud the triumph of American surgery—yet it is among the large body of country doctors, who must do all things and do them well, that observation is of the most vital importance. Having an experience that covers the entire range of medicine and surgery, they are of necessity less skillful in given lines than are the specialists.

The first thing that impresses a medical pilgrim from the country or from one of the small cities or towns is that the time

has long since gone by, if it ever existed, when it was necessary to leave America for Europe to learn abdominal surgery or gynecology.

Statistics show that so far as results are concerned American surgery leads the world. Results are what we most eagerly seek; and that surgery which gives the greatest number of recoveries is the work for us to study and to duplicate. The surgery which goes on day after day doing some ideal operation while registering a mortality of thirty per cent. may be good surgery where dissecting material is scarce and the study of pathology amounts to enthusiasm; but we, in the country, must cure our patients, or Othello-like, our occupation will be gone.

Again, until we have seen the work of others or tried, in cases of emergency, to save life by a resort to surgery, there is a deep impression that great difficulty and danger wait at the elbow of him who does abdominal work. That there is greater difficulty or danger in abdominal and gynecological work than in any other complicated surgery is a proposition that does not hold good in the presence of close observation at the operating tables of the best men in both general and special work. While the technique is exact and will admit of fewer lapses than other work it is no more exacting than should obtain in any department of the surgeon's art.

By observation and contact the country doctor and general practitioner soon learns that the Professor's chair does not always hold either a great teacher, or a great operator, and that in the case of some who write our books the pen is mightier than the scalpel. This fact makes some observation a prime necessity to him who would essay the intricate and trying work that pertains to the higher and more important surgery.

The text-book written from the library of a bungler who holds down a chair in some powerful medical school is foisted upon the readers of the profession as a guide. The old store of cuts that have done service since the time of Astly Cooper or John Hunter are resurrected by wealthy publishers ; and lurid advertisements, liberally paid for, induce the masses to buy. By just such means as this we are led to fill our libraries with a lot of trash which we find blind guides in emergencies and false teachers in the common every day practice that comes to us all. A very small amount of observation of these men in their work will soon teach us that books are often written as a personal advertisement and floated upon the market by the same means that put the authors into a surgical chair or gave them a hospital appointment.

Close observation will likewise show that medical colleges and medical professorships no longer dominate the profession as in days gone by. They are more in the nature of kindergardens where the infantile medical mind is shown the rounded globes of therapeutic systems, the perfect squares of surgical doctrine.

By observation one soon learns that as authorities teaching the newest and the best, teaching it ably and thoroughly, post-graduate schools now occupy the position that a few years back was held by medical colleges.

By seeing work done under varying conditions and with different results we readily come to the conclusion that a private hospital is by no means necessary to successful work. That the pure air of a country or village home or a clean room in a private residence in the city is as good a place for surgical work as the most painted and gilded hospital ; and, that no one need hesitate because his patient can not have the supposed advantage of some place specially set apart for the sick.

But, while recognizing and appreciating the great value of observation we can not forget that in its absence there is always room for genius to surprise by its own creations ; and we remember, with pride that the two greatest men in modern surgery, McDowell and Sims, were a product of the backwoods, and that their triumphs were worked out far from the maddening crowd.

---

**Common Mistakes of Doctors.**

1. To promise that you can render more efficient service than your fellow-practitioner.
2. To promise that your pills are not bitter or the knife will not hurt.
3. To promise that the chill or fever will not rise so high to-morrow.
4. To allow your patient to dictate methods of treatment or remedies.
5. To allow yourself to buoy up the patient when the case is hopeless.

# CLINICAL LECTURES.

## DIAGNOSIS IN ABDOMINAL TUMORS; PROLAPSUS UTERI.*

E. E. MONTGOMERY, M. D.†

GENTLEMEN: As this lecture is somewhat of an introductory one in the course, I propose to occupy a good portion of the time in consideration of the subject of diagnosis. There is probably no class of cases in which greater difficulties present themselves in arriving at an accurate diagnosis and imparting means for determining it to others, than in those affecting the pelvic organs in women. The organs most generally affected with disease are enclosed within the cavity of the body and only a part of them are to a limited degree visible, and variations in their structure must be determined to a large degree, by touch. When we consider how inaccessible they are and the difficulties attending their being outlined and manipulated, we can appreciate the uncertainty of diagnosis and the possibility of frequent mistakes; indeed, there are many abdominal growths in which even the most careful and practiced diagnostician will be led into error and it is only after the patient is subjected to exploratory incision that we can absolutely determine the pathological state.

The first patient I bring before you is a woman 57 years of age, who has been suffering from some abdominal distension for a number of years. I have not, as yet, had an opportunity to examine her and we will now do so together. The procedure is usually divided for purposes of convenience and description into inspection, palpation, percussion and auscultation. This may be followed by exploratory puncture or exploratory incision. I would not have you understand that these different processes must be followed out separately and individually, for we may very readily accomplish the inspection while palpatation or percussion is practiced. The first step, however, in examination of a patient will be to obtain her history. In so doing we learn the course of development of the disease, the influence it has had upon her general health, the relations it has displayed to certain organs, and we may form in this way some inference as to the actual seat of the disease. In acertaining the history, we take note of the age, for the reason that many diseased conditions are influenced by it; the period of life in which the individual is most likely to suffer from uterine diseases and consequently be necessitated to submit to an examination, will most likely be during the menstrual life. Prior to puberty, it is rarely necessary to make a physical examination. It is true a patient may be the victim of an ovarian cyst, or we may have collections of blood, retained menses, or a woman may be pregnant, before the menses have appeared. Examinations subsequent to the menopause are also less frequent, though disordered conditions which may be attributed to the genital organs, then demand more urgent and prompt examination than in earlier years. You would inquire as to whether the patient was married or single, her general health, and then come to the consideration of the performance of the special functions. Any diseased conditions, of the pelvic organs will necessarily influence the performance of their functions. These functions, as you know, consist of menstruation, conception, and gestation. Diseased conditions will interfere with the performance of the menstrual function, rendering it irregular, scanty, or absent, excessive, or a flow occurring without any reference to the menstruation. It may be painful, this pain preceding, accompanying or following the flow. The intervals may be attended with a profuse leucorrhœal discharge varying in color and appearance. A woman though married, may be sterile. She may become pregnant and be subject to habitual abortion. All such phenomena will have been ascertained by the history, and the presence of any of these disturbances will lead you to realize the necessity of subjecting the patient to an examination. A careful

*Clinical Lecture delivered at the Jefferson Medical College Hospital, September 26th, 1893.

†Professor of Clinical Gynecology, Jefferson Medical College; Gynecologist to Jefferson and St. Joseph's Hospitals; Obstetrician to Philadelphia Hospital.

observer may possibly have determined the diagnosis during the time the history has thus been made up; but it is important not to be governed by such conclusions, but make the examination a thorough one, and only arrive at a conclusion after all the evidence has been presented, whether ascertained through the history of the patient or by physical signs. As we have said, much may be determined of the patient's condition by a careful observation. Thus, if a patient enters your consulting room, having a large prominent abdomen, and a healthy appearance of the skin, you would possibly suppose her to be pregnant. If her face is anæmic, somewhat swollen and puffy, if she moves awkwardly, and looks depressed, you would suspect her to have a deranged condition of the kidneys, and the distension to be due to ascites; or, if with a very prominent abdomen, the face is emaciated, thin and drawn, you would ascribe it to what is known as facies ovarianæ, and suspect an ovarian cyst. These may be considered to be the indices of disease, but should not, as we have said, lead you to hasty conclusions or to determine absolutely your diagnosis until examination had been completed.

Having ascertained the history of the patient, elicited symptoms of disease and determined that there is some disorder of the abdomen or pelvis requiring physical examination, you will have your patient loosen her clothing, and if possible have had the bowels and bladder emptied, place her upon a bed, table or couch, expose the abdomen, drawing a sheet over the lower extremities and closely around the pelvis so as to prevent unnecessary exposure. Having exposed the abdomen, we are in a position to begin our examination by inspection. Through this step we are enabled to observe the amount of distension, the portion of the abdomen most prominent, the regularity of the mass, whether it is symmetrical or situated to one side, discolorations upon the skin, whether as a result of medicaments, counter irritants, or from too great tension upon it, leading to rupture of the rete malpighii and the formation of what is known as the lineæ striatæ These latter markings are very frequent in pregnancy, indeed, it is rare for a women to complete gestation without their occurrence. They have no special significance, further than that they indicate the abdomen has been sufficiently distended to lead to rupture of its middle layer. They may be found also in women with fat abdomens as a result of obesity, in women who have not born children, or from any other abdominal distension, such as a fibroid, ovarian tumor, or ascites. Not unfrequently you see in the median line, particularly in dark skinned women, a discoloration which is known as the linea nigra, extending from the symphysis to the umbilicus and sometimes to the xiphoid appendix. This line is very frequent in first pregnancies and subsequently remains. It also occurs as a result of uterine and ovarian disease. The discolorations arising from counter irritants should be noted, as they afford inferences regarding inflammatory attacks. In noting the distension of the abdomen it is well to take into consideration the portion most prominent, which indicates to a certain degree the situation of the tumor. In doing this, for purposes of more accurate study and observation, we are accustomed to divide the abdomen by imaginary lines into nine spaces, and remembering the viscera that are to be found in the different tracts of the abdomen, we are enabled to form an inference as to the particular organs involved in any individual growth. Inspection is followed by palpation, or the latter may take place during the time we are inspecting the surface. Palpation is practiced by placing the fingers of the two hands, previously washed and warmed, over the abdominal surface, sometimes bringing the entire mass between the fingers, and at other times moving them close together; in so doing we determine the sensation of fluctuation. By inspection we may frequently witness the protrusion of the abdomen, resulting from the movements of the fetus within it, and this may be readily recognized by palpation. In addition, this enables us to appreciate the sign pointed out by Braxton Hicks, of the regular rhythmical contractions and relaxations of the uterus distended by pregnancy. Fluctuation and wave-like motion is determined by placing the hands upon one side of the abdomen and gently striking the opposite side of the abdomen with the other hand. A wave of fluctuation will differ in length according to whether the cyst is a single one, or made up of a number of smaller

cysts. A shorter wave of fluctuation indicates that it is made up of a number of cysts, or the cyst wall is divided by a number of partitions, and these may be so numerous that instead of fluctuation we will have an indistinct sensation of elasticity, leading us to recognize that we have not a solid tumor. Any irregularities or projections from the surface of the tumor are readily recognized as it is being palpated.

We come now to the consideration of percussion. This is of special value in differential diagnosis between solid and cystic growths and fluid that is free in the abdominal cavity. Thus, in ascites, though it may lead to marked distension of the abdomen, yet upon percussion the zone of resonance will be found at the summit of greatest distention, while around the sides dullness will result. This is due to the fact that the intestines being filled with gas are lighter than the fluid and consequently float to the surface. There is, however, a possibility of error in this in marked distension, as the mesentery may be too short to permit the intestine to come in contact with the abdominal walls. A layer of fluid consequently intervenes, giving dulness upon percussion. If the percussed finger is pressed deeply into the abdomen, the intervening layer of fluid will be displaced and resonance result, hence dullness upon superficial and resonance upon deep percussion. In fluid contained within a cyst, as it increases in size the intestines will be pushed upward and to the opposite side, so that we shall have resonance upon one flank. This resonance indicates that the tumor has probably arisen from the opposite side. In ascites it will be remembered also, that the level of resonance will vary with the position of the patient, while in a solid or cystic growth, it does not change. The importance of these signs cannot be over-estimated and should always be taken into consideration in every case. That it is not always appreciated I can demonatrate to you by a recent case of my own experience. A woman 42 years of age, had had an abdominal distention for 18 years. This had been diagnosed as a cyst years ago and an operation advised but refused. Several weeks before she came under my observation she had been confined to bed suffering from pain, marked elevation of temperature, reaching at times as high as 103°; she had become emaciated and much enfeebled. The abdomen was very prominent and was nearly symmetrically developed and fluctuation was very distinct. In percussing over the abdomen there was a peculiar resonant note extending well up over the left side. This note was that of a canal containing air, the walls of which were pressed in contact by percussion. It was recognized as probably the colon, but its particular significance was not estimated. The length of time the cyst had been in development led me to suppose that I had to deal with a parovarian cyst. The patient was subjected to operation, and upon opening the abdomen, the peritoneum was recognized as covering the portion of the cyst exposed. The opening was enlarged, hand passed over the mass and it was found that so far as it could be reached, it was covered with peritoneum. The trocar was introduced, drawing off four gallons of fluid; peritoneum was found open and the cyst wall enucleated, removing a mass which weighed 18 pounds, without having ligated a single vessel. Looking into the cavity after its removal, the whole left side of the abdomen was laid bare behind the peritoneum from the diaphram to the pelvis. The left kidney projected as a cyst into the surface. Its vessels consequently were ligated and the organ removed. It was found to be a sacculated kidney. Now, the point I wish to make with reference to this case was, that had we appreciated the significance of the situation of the colon, and its relation to this mass, we would recognize that we had to deal not with a parovarian or ovarian cyst, but what was actually present, a retroperitoneal cyst. Such recognition might in some cases have been of advantage in leading us to have made our incision in such a way as to open the peritoneum outside of the colon, instead of within it, as we did in this case, thus increasing possibly the peril of the patient by diminishing the chances for the nutrition of the large intestine. Fortunately, however, in this patient there was no inconvenience experienced, and though the operation was done over three weeks ago, the patient has recovered as rapidly as she would after the removal of an ordinary uncomplicated cyst.

Auscultation in abdominal work is of advantage in enabling us to hear the blood coursing through the uterine sinuses and to determine the fetal heart sounds. The latter symptom, once heard, can be mistaken for no other, and would of course determine absolutely the presence of pregnancy, even though a tumor were present. Having thus considered the method of determining the symptoms, we return to the patient before us and endeavor to put in practice what we have just discussed and thus ascertain if possible the character of the abdominal distension. As we look at the abdomen, we notice that it is not symmetrical; it is much more prominent upon the left side, and as I pass my hand over it I feel an irregularity or mass projecting from a hard, firm growth. This growth extends down into the pelvis, evidently showing that the tumor has arisen from below and developed upward. This is indicated, also, by the intestines having been pushed upward and to one side. You notice, also, that the tumor is movable, can be moved from side to side and pushed upward. The age of the patient, over fifty years, would exclude the probability of pregnancy; then, too, as we return to the history of the patient we find that it has been in existence for fifteen years. This, taken together with its size and resistance, will eliminate the probability of pregnancy and at the same time demonstrate that we have a solid tumor which has arisen from the pelvic organs.

Now, the only organs in the pelvis from which solid tumors are likely to arise are the uterus or the ovaries. That this tumor was not an ovarian growth may be concluded, first, from the fact that such growths of the ovary are rare and do not attain to a size such as this patient presents. unless from malignant disease. Such a growth would not have been in existence for so long a time and would have given rise to much more pronounced constitutional symptoms. Her Her menses ceased at fifty-two; this was a prolongation of the climacteric, but not an unusual one in women who suffer from uterine growths. The presence of such a growth keeps up the congestion in the organ and consequently the prolongation of the menstruation. Now, as we return to the history, we find that this patient has not suffered from severe hemorrhages. Her menses ceased five years ago, and she has had no return. While we do not have any history of hemorrhage, we have no hesitancy in believing this to be a fibroid tumor of the uterus. You will remember that the class of tumors which are most likely to give rise to hemorrhage are those fibroids which have had their origin near to the internal surface of the uterus, and as they have subsequently developed have pushed the mucous membrane before them, interfering with its circulation and thus cause hemorrhage to take place. The relation of this tumor to the uterus and the other pelvic organs could be determined more accurately by a vaginal examination in conjunction with abdominal palpation. Indeed, we would not proceed to an operation in such a case without having had a preliminary vaginal examination.

*Prolapsus Uteri.* The next patient I bring before you is a woman sixty-four years of age, who has suffered from a protrusion of the vulva. As she lies upon her back and the limbs are separated you see a mass lying between them which covers over the vulvar orifice. In looking at this mass you will notice anteriorly an opening looking directly forward, which you will recognize as the external os. As I place my hand over it posteriorly I find that the uterus had been retroverted and displaced and that the entire posterior wall of the vagina is inverted. We have consequently, a hernia of the uterus and vagina. As I place my hand upon its posterior surface and push up so as to place the uterus parallel to the axis of the canal of the pelvis, we can readily reduce the hernia. Having placed the uterus in this position, by pushing upon it the entire surface is carried backward and the organ replaced. Of course the mildest effort at straining or assumption of the upright position leads to its redevelopment. The patient cannot be in a much more uncomfortable state than with such a displacement. The organ protruded between the limbs, is subjected to friction against the clothing and against the limbs, the urine and feces flow over it, the thorough evacuation of the bladder cannot be readily accomplished, portions of urine remain, decomposing and producing irritation; in some cases this leading to the formation of deposits and the development of large cal-

culi. The interference with the circulation in the prolapsed tumor not unfrequently leads to ulceration of its surface, so that a large portion of it is ulcerated. In a woman 64 years of age, the outlook for a recovery after operation is not good; even should temporary cure be secured, the tissue will soon break down by pressure and the condition redevelop. In this patient we would prefer to advise her to have some form of pessary with external support by means of which the organ can be raised and kept up, thus giving her relief for the few remaining years of life that may be spared her.

## COMMUNICATIONS.

### "CICATRICIAL STRICTURE OF PYLORUS; PYLOROPLASTY."*

A. M. CARTLEDGE, M. D., Louisville, Ky.

J. F., age thirty-eight years, native of Germany, presented himself to my notice Sepetember 7th, 1893, with the following personal history. He was a robust youth and enjoyed perfect health until twenty-six years of age. At this time he observed (as he remembers) the rather sudden appearance of pain near the center of his stomach. This pain was intermittent in character but at times very severe. The services of several physicians failed to relieve him. Some four years later when about thirty years of age, he noticed the location of greatest pain and tenderness had shifted to a slightly lower plane, and more to the right (his description and location placing it about the liver notch). So far as he could remember this change in the situation of pain was gradual. The subsequent eight years of his history is one of varied suffering and symptoms. The intermission of the pain and a fixed and constant tenderness were always characteristic. During these years he noticed the passage per rectum of large quantities of a gritty substance resembling sand. Dejection of spirits and progressive emaciation were pronounced; no nausea or vomiting; appetite usually poor but variable; thinks he was slightly jaundiced two years ago. The physicians diagnosed "gall stones." From January 1st., 1892, to October of same year, suffered pain almost constantly, was unable to attend to any business. At this time, October, 1892, was examined by several physicians with a view to operation. One of these, a surgeon, gave him great pain in manipulating the affected region. He was told to examine his stools and save any concretions that might pass. Two days after he found in a fecal evacuation a large size ordinary pin, much augmented in size by the adherence of deposit. He felt much relieved after the passage of the pin; the nagging and lacinating character of the pain left him, also a swelling that the physicians and he could distinctly feel before. His improvement, however, did not lead to health restoration. Pain and discomfort together with some tenderness remained. and has shown no disposition to lessen during the past year.

PRESENT STATUS:

A man fairly nourished, of good color, sad expression, tenderness over region of gall bladder, and to the left. Deep palpation detects a slight enlargement in region of gall bladder Palpation and percussion reveal an enormous distension of stomach, extending from the fifth intercostal space to a line on a level with the umbilicus upon the left side. Heart's action unusually slow and steady, no murmur, pulse 60, no vertigo or other cerebral manifestations.

Diagnosis uncertain; certainly there was stenosis in pyloric region, with everything pointing to it being of cicatricial origin. There was a possible gall bladder trouble in addition. With a plain statement of the facts to the patient, an exploratory operation was advised, and accepted.

September 11th, assisted by Drs. Sherrill, Satterwhite and Buren, the operation was performed. The usual incision for exposing the gall bladder was first made. The organ was found comfortably distended, but soft and pliable, palpation detected nothing but fluid in the cavity. To make doubly sure that this fluid was

*Abstract of Essay read before meeting of Louisville Medico-Chirurgical Society, September, 1893.

bile and that no obstruction existed, the needle of a hypodermic syringe was introduced and pure bile withdrawn.

A semicircular incision was now joined to the upper angle of the first cut, the convexity directed downward and carried to about the center of the epigastric space. This incision severed the right rectus completely. The distended and dilated stomach soon presented and was with difficulty kept back by flat sponges. A search was made for the pylorus, which was with some difficulty found. A marked thickening and induration was found, but very narrow, not more than one-half inch in width. There seemed to be an unusual fixity of the pylorus, rendering its exposure difficult. The operation of pyloroplasty devised by Heineke and later by Mikulicz was performed.

Upon opening the stomach there was quite a little gush of mucus, nothing else, and there was a very notable collapse of the stomach from the gas that passed out. The stomach up to this time was enormous in size as I have already stated, but could be easily compressed after the opening by the use of a flat sponge. After suturing, the edges a strip of gauze was carried down to the point of suture and brought up and out at the middle of the wound. I did this not that I feared so much the ability of my suture to hold, but from the fact that there had been an escape of mucus and I feared infection of this region and preferred to practice drainage. There was considerable hemorrhage from the surrounding structures in handling the stomach, and getting this out was attended with considerable difficulty, consequently I deemed it advisable to insert the gauze. The lower angle of the wound was drained in the same way. The progress of the case was not as uneventful as I would like; the man developed some fever, temperature 102 F., he has suffered considerable pain necessitating the use of some morphia at various times; has taken probably about one and one-half grains at different times since the operation. Recovery seems now assured; there is no evidence of leakage whatever. The patient was nourished exclusively by the rectum with peptonized milk for three days. The least possible amount of water was given by the stomach. He was then given beef tea, later peptonized milk by the mouth, and now for four days he has been taking strained soups, etc. As already stated there has been no evidence of leakage up to the present time, and certainly there is no reason to expect there will be any now. There is still some little discharge at the point where the gauze points down to the pylorus; the lower drainage wound has entirely healed.

At the time this operation was first brought out, it struck me as being one of great interest. First, the ingenuity of the operation; second, the fact that physicians are very apt to overlook the very common occurrence of pyloric stenosis the result of cicatricial contractions. There are a great many characteristic symptoms representing pyloric obstruction, which might easily be overlooked on the ground that we have heretofore called these "gastric catarrh," where we have atony of the gastric walls as a result of catarrhal condition.

This operation for the few times it has been performed, is certainly successful. Heretofore, as you are probably aware, the operation of Loreta was most common, that consisted of making an incision in the stomach near the pylorus, and, if any stricture of the pylorus was located, it was divulsed and then the wound in the stomach was closed. This operation was found to be followed by about the same results that divulsion of stricture in other portions of the body; that is, there was a speedy return of the trouble—contraction of the divulsed structures soon took place and the patient relapsed to his former condition. In the future if we look out, I think we will find many more cases of pyloric stenosis than we have heretofore supposed.

In the case reported by me to-night, the patient never had any nausea or vomiting; the trouble was cicatricial stenosis as the operation proved beyond a doubt. Another interesting feature was the pin; there can be no doubt but this pin was lodged in the stomach for the last eight years, although the patient has no recollection of ever swallowing it, and the last four years it has been near the pylorus. The changes in character and location of the pain I take it were due to the migration of this pin, and the continuance of distressing symptoms after passage of the pin per rectum was owing to cicatrization in the pyloric region causing stenosis in this locality.

Note. The patient has since made a very happy recovery.

# THE IMPORTANCE OF EARLY ATTENTION TO THE DISABILITY CAUSED BY INFANTILE PARALYSIS.*

A. B. JUDSON, M. D.

I propose to consider briefly the question whether a certain class of patients should not be committed more entirely and more early than they are to the care of the orthopedic surgeon, a consideration as interesting to the family physician as to the orthopedist, as they meet in a friendly alliance to secure the greatest benefit for their common patient.

I refer to patients disabled by infantile paralysis. The child has passed through stage of onset. Ergot, electricity and massage have produced their legitimate effect, and we will say that the eighteen months, which are believed to be the limit of spontaneous recovery from the paralysis, are passed. The friends and the patient, with many grievous misgivings, have become reconciled, or at least accustomed, to disability and deformity which now seem to change for neither the better nor the worse. What can now be done? The question whether such a patient may not yet receive benefit from the advance of scientific knowledge, or from the daily increasing facilities for the application of knowledge, will surely spring up in the parental heart.

Now it is curious to note that the deformity in these cases is often found, upon analysis, to be a disability more than a deformity. Take a case, for example, in which the knee cannot be completely extended. When the patient is sitting there is no deformity, but when he stands the apparent deformity is due to a disability —an inability to extend the knee. How easy it would have been to prevent contraction of the hamstrings by providing for their repeated elongation by complete extension of the knee, easy comparatively for one who has given himself to such details and is habitually mindful of their importance and free from the manifold cares which beset the average practitioner. And it should be borne in mind that cases sometimes occur in which shortening of the tendons begins, in a manner not well understood, at a very early stage, before simple desuetude can be fairly accused of being the author of the mischief. The prevention of muscular and tendinous shortening then should receive attention on the part of the early observer of the case. It is not an obscure and difficult point, but one which has perhaps escaped the consideration to which it is entitled.

To recur to the disabled knee, and this part of the anatomy is used simply as a convenient example to illustrate points in pathology and treatment applicable to all the joints, if the knee is kept extended at those times when walking is attempted, not only are the muscles and tendons kept in normal elongation, but the general welfare of the limb is assured. Neglected patients may be seen in the streets walking laboriously, with extension of the knee produced by the hand pressed firmly, at every step, on the lower part of the thigh when the weight of the body is on that limb. It is doubtful whether this in any case prevents the final resort to a crutch, by the use of which the limb is made to dangle, being carried about as a worse than useless burden, twining limb around the crutch, subject to the painful affections which attack the lower extremities in cold weather in the absence of healthy circulation, and more and more impeding locomotion until, as has happened many times, the adult patient seeks relief and improved locomotor ability in amputation and an artificial limb. If the knee is stiffened mechanically the pressure of the weight of the body in standing and the repeated concussion of the limb, as the foot strikes the ground in walking or running, will improve the tardy circulation, but beyond this, and better than this, will be the development of unused muscular fibres and special groups of muscles, by whose action important motions will be acquired which would have been impossible if the limb had remained in suspension.

Now in order to keep the knee firmly extended under the weight of the body in standing and walking, and to give use and development, as far as may be, to the fragmentary muscular system of the limb, apparatus is required; but it will not be

*Read before the New York Academy of Medicine, November 2, 1893.

obtained without authorative medical advice and prescription, and as a rule the family physician cannot be expected to work out the tedious processes incident to treatment of this kind. It falls to the lot of the specialist, who can well bear the inconvenience attending final results which are more or less imperfect, after satisfying himself that he has done all that science permits to be done, and whose daily and hourly mastery of the necessary details has enabled him to reduce perplexing and complicating conditions to familiar routine. Treatment of this kind lies far outside ordinary practice in which the physician renders such signal service. He makes his diagnosis, advises, prescribes, remains on guard against complications, forsees the crisis and prepares for it, leads the way cheerfully through convalescence, and medical science, so dear to us all, finds but another illustration of its power and beneficence. In one home a wasting fever has been finally resolved and the patient rises in perfect health from a bed where the grim alternative has been decided in his favor. In another the children have been happily carried through the perils of infection and resume their places at the table. But in the special practice adapted to the cases under consideration there is no fear of a fatal result and no rejoicing, and the object sought is at the best a palliation. But who will say that important service has not been rendered? For it should be remembered that the conservative and plodding practitioner along this line has for an ally one of the most potent influences in Nature in the growth of the body. The popular reliance on this force, expressed in the common question—"Will the child not outgrow the ailment?", whatever it may be, is not always misplaced. Happy the physician who, imparting his confidence to the patient's friends, and relying on the exact science of the physicist, sees grace and power growing out of deformity and helplessness.

A good general rule in the treatment of deformity in a growing child is to keep the part as near as possible in the desired shape as much of the time, day and night, as is practicable, so that the increment shall be on the right side of the dividing line between the normal and abnormal. The familiar proverb says: "As the twig is bent, the tree's inclined." In the troubles following infantile paralysis the principle should be extended. We should not only persist in keeping the part as near the normal shape as we can, but we should also give as wide play, as the crippled condition of the limb will allow, to the functions of motion and weight-bearing. From the very earliest attempt to walk, or to make use of the muscles and joints which are imperilled by the cord lesion, extraneous assistance should be afforded. It should not be said, off-hand, that the child is too young. The first and repeated question should be: Is the child not yet old enough, or is he not already giving sufficient evidence of a desire to make use of the questionable muscles and joints to make assistance desirable or necessary?

When efficient treatment is begun it is easily continued. Improved ability is at once appreciated by both parent and child. It is well that such is the fact, for improvement does not stop with infancy or childhood. The process is slow and prosaic, but the benefit cannot be overestimated in the opinion of the one who is in the best position to judge of its value. A slight improvement in the gait, or ability to walk a little faster or a little further without fatigue, confers lasting happiness, and the patient and physician are thus encouraged to go on to new achievements until, with one step after another gained, the outcome is an adult well able to follow the ordinary pursuits of life, in place of a being who had looked forward to hopeless dependence.

---

A famous surgeon went once to see a lunatic in a private asylum, and in passing through a corridor, he was thus accosted by one of the patients: "Take off your hat, sir?" "Why should I?" he asked. "Because I am the son of the Emperor of the French." "Oh, I beg your Royal Highness' pardon," apologized my friend, taking his hat off. On revisiting the asylum a month or so later he was again accosted in the same corridor by the son of the Emperor of the French, and in the same words: "Take off your hat, sir." "Why," asked my friend. "Because I am the son of the Emperor of Germany." "Surely when I last had the honor to see your Royal Highness you were the son of the Emperor of the French?" "Ah, yes," he added, "That was by another mother."

## A DEPARTURE IN THE TREATMENT OF BRIGHT'S DISEASE.

W. H. WALLING, M. D., PHILADELPHIA.

The pathology of this affection will not be considered further than to state that in many cases diagnosed as Bright's disease, the lesion may be in the heart and not in the kidneys, the albumen being the result of a passive congestion in the kidneys, due to a defective circulation. In such cases a proper regulation of the circulation will materially reduce, if not altogether remove the albumen.

The diet is of prime importance in the treatment of albuminuria. Eminent authorities direct milk, vegetables, white meat of chicken, eggs, but little or no beef or other meat. One prominent practitioner recommended the albumin of eggs, but forbade the use of the yolks, while another reversed this order, and forbade milk, but allowed butter. Taking these various recommendations into consideration I concluded to give each method a fair trial in a case of albuminuria and carefully note the result.

The fact that chronic Bright's disease existed was shown by repeated examinations both chemically and microscopically, as well as by high tension of the pulse and other symptoms. The amount of albumen was about one per cent.

Treatment was commenced in Dec., 1892, and consisted at first of steam baths and electricity, with tri-weekly sittings, which kept the skin in good condition and tended to relieve the kidneys. The various drugs used in such lesion were administered *pro re nata*.

The diet consisted of vegetables, eggs, stale bread, chicken, oysters, some milk, but with little meat. The appetite was very capricious and but little could be eaten. Flatulance; nausea (sometimes amounting to vomiting of fermented food); general distress; headache of a severe type, were constant factors. There was also a severe hyperesthesia of the rectum vagina and urethra. Sleep had to be induced by various hypnotics, chloralamid proving to be the most powerful of all used and very satisfactory. Opiates were not resorted to except in a very few instances to control excessive pain.

After several months of the regulation diet, the patient was placed upon an exclusive meat diet, after the method of Dr. Salisbury, which consists of lean beef finely chopped in a suitable machine, after having all the fibrinous and fatty portions removed. It was then broiled quickly, served hot, being salted to taste. A little butter was allowed; toasted brown bread, tea or coffee with a little milk but no sugar, constituted the balance of the diet. One hour before each meal, and at bed-time one or two cupfuls of hot water acidulated with lemon juice, were given. Fruit was added when peaches came into market. The appetite improved, strength began to return, there was no more nausea, and but little flatulence.

Iron being prescribed by all authorities, I looked about for the most readily assimilable, palatable, and convenient form in which to administer it, and found it in the *albuminate* of iron, which was brought to my notice by reading reports of its use in European medical journals. This had a most marked effect upon the character of the blood, as shown by the great increase of the red blood corpuscles. For a time iron was omitted the want of it being at once felt.

Again, to more fully test the value of the beef diet, it was discontinued for about two weeks, and eggs, vegetables, etc, given, the result being a return of nausea, loss of appetite, flatulence, an increase of distressing heart symptoms, and a general decline in vitality. A return to the strict beef diet, with some fruit, and the iron as above, the appetite rapidly returned, and the strength correspondingly increased.

The albumen, which had been reduced to 0.50 per cent. increased during the cessation of the beef and iron to 0.65 per cent. declining again upon their resumption.

As a heart tonic I have given granules of digitaline gr. $\frac{1}{67}$ or strophanthin gr. $\frac{1}{100}$ with nitro-glycerine granules $\frac{1}{120}$ as indicated. A combination of several of the more important heart tonics has also been very useful.

Contrary to an opinion expressed by some practitioners, the hyperæsthesia alluded to was not caused by the beef diet,

as it existed long before that was entered upon, and was lessened by it. Local applications of iodoform were attempted, but quickly abandoned, as that drug greatly aggravated the condition. Aristol, administered in hollow suppositories or gelatine, served a much better purpose.

I shall continue the treatment so long as the patient continues to improve under it, which she is now steadily doing.

I have placed patients suffering from locomotor ataxia, spinal irritation, Parkinson's disease and other kindred disorders, upon the exclusive meat diet, with great benefit. The use of the hot water one hour before meals and at bed-time is essential in most cases. Lemon juice to taste is desirable. It may also be used on the meat in place of vinegar.

A rigid adherence to the diet as prescribed by the physician is essential to a cure.

# SOCIETY REPORTS.

## THE LOUISVILE MEDICO-CHIRURGICAL SOCIETY.

*Meeting of September 22, 1893.*

### CASE OF DOUBLE HYDROCELE.

Dr. W. L. Rodman: This gentleman, forty years of age, comes from the southern part of the State, and presents a condition that, as far as my experience is concerned, is rather uncommon, especially in a man of this age. Four weeks ago he noticed a swelling in the right side of the scrotum and now the enlargement extends to both sides but is not so marked in the left. I have made diagnosis of double hydrocele. The right side presents the typical appearance and shape of a hydrocele, so tense that fluctuation is elicited with difficulty. The amount of fluid in the left side is not great, yet there is some. The patient thinks that the tumor of the left side varies considerably in size and position. I made a careful examination with the patient in the recumbent position but was unable to produce any appreciable diminution in the size of the tumor by manipulation. Another interesting feature is that the trouble began only four weeks ago; I think it is unusual to find a hydrocele attain such size as this has done in the right side in so short a time. There is no history of traumatism, or other assignable cause for the trouble.

I shall perform the same operation that I usually do in cases of this character, *i. e.* inject carbolic acid.

### DISCUSSION.

Dr. A. M. Cartledge: I have seen several cases of double hydrocele, but they have usually been in older men, and followed degenerations from epididymitis, etc., but the history of this case dating back only four weeks, attaining the size it has in that length of time, and the peculiar feeling of the left side which is not so developed, I think throws at least a suggestion upon the case. The cord structures of the left side seem to be very much enlarged. The vas and blood vessels also. I take it that we have, in this case, a purely symptomatic hydrocele, and there are serious changes going on within the structures of the scrotum. Of course little can be told in regard to the right side until the water is drawn off. The left side presents several suggestive features. I think that it is probably an acute tubercular lesion. From the feeling, the left side would indicate extensive infiltration of the cord structures with tubercle, and I believe Doctor Rodman will find the same condition existing on the right side after withdrawing the water. In my judgment the whole trouble is the result of changes purely in the cord structures, affecting the circulation,

Dr. W. O. Roberts: As the trouble has existed for so short a time, I asked the question when he was examining the tumor, whether there was any hardness about the cord or epididymis. I think it is possibly symptomatic. It has come on too rapidly to be simply a pure hydrocele.

Dr. W. C. Dugan: (Visiting) I take it that this case is peculiar, inasmuch as both sides are involved. But I have seen

in the last two years, two cases of acute hydrocele in old men, that came on in a few hours. One of them I remember developed in three or four hours; the patient was thought to have a strangulated hernia. The tumor on one side was as large as a child's head, containing over a quart of very clear fluid. Believing the testicle was diseased I removed it and the cord, very high up. There was no evidence of any pathological lesion at all in that case revealed on the most careful examination after removal. It was much atrophied as would be expected in very old men. The cause of the trouble I am unable to explain, but that such conditions are met with is known to every practical surgeon.

Dr. W. L. Rodman: The left side as Drs. Cartledge and Roberts state, presents an unusual appearance, and it led me to make a very careful examination. The right side seems to be a typical hydrocele. I admit that the course of this trouble is unusual, and, yet, it is a fact that we do have acute and chronic hydroceles. While it will not often be found that a case of hydrocele will attain such a volume in four weeks, they do run such a rapid course at times. I am inclined to think this is simply a double hydrocele without any tuberculous lesion at all. The man's age is rather against tubercular change in this region. Young subjects are more apt to present tubercular epididymitis than men forty years of age, and while I admit that the condition is a little unusual, at the same time I think that this is simply a double hydrocele of the acute variety. I have seen hydrocele appear and disappear inside of a week or ten days; they sometimes come on very rapidly. Hydroceles which pursue this course are, as a rule, small, and absorption is rapid. I do not believe there is any tuberculous change in this case, but I shall make a very careful examination to-morrow when I operate on him, and report at the next meeting. One point I neglected to mention in giving the history of the case is, the man has never had any pain in the testes, and no fever.

---

### SUPRAPUBIC CYSTOTOMY FOR REMOVAL OF TWO STONES FROM BLADDER.

Dr. J. L. Howard: I present here two stones removed from the bladder of a man seventy-three years of age, by the supra-pubic operation. The only interesting feature about the case is the character of the stones. I had one of them cut in two. It shows the uric acid nucleus beautifully; one layer of uric acid, then a layer of lime.

#### DISCUSSION.

Dr. W. O. Roberts: Nearly always in old men the stone is phosphatic in character. I removed three stones from the bladder of a man sixty-seven years of age, and two of them were decidedly phosphatic, the third mixed. I would like to ask Dr. Howard if his patient had any difficulty in passing water from prostatic troubles.

Dr. J. L. Howard: At the time of the operation he had no prostatic trouble whatever; however he had a prostatic enlargement secondary to the operation. About a week afterward, in attempting to close the external wound by tying a catheter in the urethra, I found it impossible to insert a straight catheter, but finally succeeded in passing a prostatic catheter. The enlargement subsided in about ten days. The drainage employed was gauze; the abdominal wound united readily, and the patient had no trouble in passing water for the last three weeks. The operation was performed six weeks ago. He passes water now only about every three or four hours, while heretofore it was every few minutes.

Dr. W. L. Rodman: I assisted Dr. Howard in the operation referred to, and saw the patient about a month thereafter, and he was entirely relieved of all symptoms. I have never seen a case of lithotomy followed by better results.

Dr. W. O. Roberts: Do you know whether this man had any history of renal colic at any time?

Dr. J. L. Howard: No such history could be elicited.

---

### FATTY TUMOR.

Dr. W. O. Roberts: I have a specimen here not much in itself, but of interest because of the location in which it was found. The patient was a child three years old. This tumor was first noticed two years ago—that is when the child was one year old—located on the palmar surface of the hand between the fourth and fifth metacarpel bones, near the phalangeal articulation. I saw it for the first

time about a month ago. It was then of considerable size and kept the fourth and fifth fingers widely separated by its pressure. Upon examination I was led to believe from the location of the growth and from the hardness of it, that it was an enchondroma, but when it was cut down upon, much to my surprise I found it to be simply a fatty tumor.

DISCUSSION.

Dr. W. L. Rodman: This is one of the regions of fatty tumors, but enchondroma are much more common. The fleshy part of the palm is the only portion of the hand where lipomas are found.

Dr. W. O. Roberts: Some time ago I removed one three times as large, from the ischio-rectal fossa of a child three years of age.

---

IRREDUCIBLE HERNIA—OPERATION; ABSCESS OF THE OMENTAL STUMP—RECOVERY.

Dr. W. L. Rodman: This specimen was removed from a gentleman thirty-three years of age, who had had a hernia upon the right side for several years. It had been reducible until a few years before he was brought to me. It had become irreducible, the patient was having considerable pain, and while the physician in attendance did not think the hernia was strangulated, yet he believed it was a favorable case for operation. It was a very large epiplocele, the largest I think, that I have ever seen. The omentum was so large that I divided it into four equal sections and ligated each with cat-gut. The operation was done after the method of Kocher, of Berne. I have done quite a number of similar operations in the last year, and all of them have done absolutely well, except this one. The man is now perfectly well. He did not have a bad symptom until the thirteenth day. Then I noticed a swelling in the right iliac region and I at once thought there was some trouble with the omental stump. A short time before performing this operation I had read an article by W. T. Bull, of New York, in the *Annals of Surgery*, in which he calls attention to this complication. So far as I know he is the only one that has done so. He reported two or three cases; one in which an abscess of the omental stump occurred as late as six months after the original operation. This is what occurred in the case reported by me to-night. After the tumor attained the size of a doubled fist, it broke; he has since had entire relief and there has not been a bad symptom. It is the first time I have seen a complication of this kind, and would have been at a loss to understand it had I not read Bull's article a few weeks before. The stump was ligated with cat-gut and the sac, ligated with silk was pulled out so as not to leave an infundibulum to induce return of the hernia. In none of the cases upon which I have operated, has there been any return of the hernia. The first operation I did according to this method was eighteen months ago. I have had no death.

DISCUSSION.

Dr. A. M. Cartledge: I was especially interested in the report of cases by Bull, referred to by Dr. Rodman, concerning trouble with the omental stump, as I had recently had two. One was a very large epiplocele in an old woman; the whole mass was carefully ligated away, and the stump returned. Later she developed (the hernia was on the right side) quite an induration high up in the abdomen, which was very sore and tender, and I was at a loss to know its true nature. Just about that time Bull's article appeared, and I at once recognized that the trouble was in the omental stump. The patient had several attacks of circumscribed peritonitis, which finally subsided and she made a good recovery.

The other case was one following a ventral hernia that occurred after laparotomy had been performed twice. The third time it was followed by a ventral hernia, and upon opening up the structures it was found that the omentum was adherent in the left iliac fossa, having become very tense and thick. This was stripped up, the lower attachment tied off with a silk ligature and the operation completed. Subsequently this woman developed a hard induration in the left side of the abdomen, which finally led to another exploration. I thought I could demonstrate the existence of pus. There was some elevation of temperature, going as high as 101° F. After several months I made an incision and we were very much puzzled because of the extent of the induration and its location, it being so low down. After searching thoroughly and finding nothing, I simply had to close the

wound. However, I inserted a small gauze drain at the bottom. This remained for some days and was then removed. She seemed somewhat better and went home. Every night the opening where the gauze drain came out would fill with serum and discharge. This kept up for five or six weeks, and finally the old silk ligature that was around the omentum came away. Since that time she has been perfectly well, showing that the irritation was really due to the silk ligature around the omental stump.

I believe in these cases cat-gut instead of silk should be used as material for ligature and, in tying off large masses, the omentum should be divided into sections. I can look back now, and see other cases where the omental stump has probably been the cause of trouble, but these two cases occurred just prior to the publication of Bull's report of three cases which terminated in resolution, and one in death—a total of four cases. One of mine terminated in resolution after passage of the silk ligature; the other terminated in resolution after rest, warm applications, etc.

---

Dr. A. M. Cartledge read an essay on "Cicatricial Stricture of Pylorus; Pylerplasty." See page (745)

DISCUSSION.

Dr. W. O. Roberts: I have under observation now a young woman, who, a week ago swallowed a pin. She has been complaining ever since of pain in the region of the pylorus, and there has been a doubt in my mind as to whether or not an operation would become necessary for its removal. There is considerable tenderness in this locality, but there has as yet been no fever, no vomiting and apparently no difficulty in the discharge of food from the stomach. I shall watch the case with great interest, and in the event operation becomes necessary shall adopt the method described by Dr. Cartledge.

Dr. W. L. Rodman: I have had no personal experience in cases of the character under discussion. I rather think, as Dr. Cartledge says, that possibly these pathological conditions are more common than is generally supposed. It is remarkable how pins and substances of like nature can be retained in the alimentary canal and tissues surrounding it, for so long a time. I remember, while serving as physician in the Kentucky Penitentiary, to have opened an abscess in the abdomen of a convict, and out of this abscess I removed three headless pins. The man had been a painter in Louisville, and had been in the Penitentiary for about twenty years. He told me that while following his vocation he was in the habit of taking pins with the heads cut off into his mouth and frequently swallowed them. As he had swallowed no pins since he had been in prison, it is evident that those taken from the abscess had been in the body for over twenty years.

Dr. J. A. Larrabee: While the subject of pins is under discussion, I would like to mention one case which may be of some interest. The patient, a child three and a-half years of age, complained of rectal trouble from which she could get no relief. An examination revealed a safety-pin pinned into the lining of the rectum. There was no history or knowledge on part of the child or mother of a pin having been swallowed and how it got there is a mystery.

Dr. L. S. McMurtry (Visiting): The case reported by Dr. Cartledge seems to me to be very unique. I think it demonstrates that surgery of the stomach is destined, in a very short time, to take a place with surgery of other parts of the alimentary canal that will make it thoroughly practicable. The trouble has been that operations of this class heretofore have been done only for malignant disease and in cases where the patient was in a dying condition, which is not a fair test for any operation; but it seems that this is the crucial test of nearly all new operative procedures, especially in abdominal work. I think the case Dr. Cartledge has reported, which resulted so happily, should encourage more frequent operative interference in troubles of this kind. Take for instance the case of Dr. Bernays, a celebrated case where a juggler was in the habit of performing the trick of almost swallowing a case-knife, allowing it to pass down the œsophagus. One evening it slipped from his fingers and passed into the stomach, and an operation was performed for its removal within a couple of hours. The stomach was opened and the knife taken out, the wound was carefully closed in about the manner Dr. Cartledge has described, and

the man made an uninterrupted recovery. There we have something like a fair test of what can be done in skilled hands in opening the stomach. The case reported by Dr. Cartledge is just in the same line. The patient did not have malignant disease, but did have a disease which certainly justified heroic steps in order to bring about a cure.

There is only one point upon which I could criticise Dr. Cartledge's technique, and I do not know that I have the right to do that, but I think it would have been better done without gauze drainage. I believe that to have inserted a drainage-tube which could have been emptied every fifteen or twenty minutes and the tube removed at the end of twenty-four hours, would have been preferable. I do not think in any case where we want to drain away blood or mucus, that the gauze drain is advisable. If you will notice a capillary drain drains almost entirely serum. The lymph becomes entangled in its meshes very rapidly and makes it difficult to remove after twenty-four or forty-eight hours. When it is necessary to drain at all, it can be better accomplished by an open drain and suction than by gauze. I believe that the patient would have recovered without drainage, but in the choice of drain I would have been disposed to select a tube.

Dr. A. M. Cartledge: This operation, as I have said, originated with the two men, Heineke and Mikulicz, from the fact that Heineke described the operation, and, eleven months afterward, Mikulicz performed it with entire ignorance that it had been devised and described by Heineke. For this reason the operation was named after both gentlemen. They advise that the incision shall be through the pylorus, and then extend one inch up into the anterior wall of the stomach and one inch into the wall of the duodenum. In doing the operation it struck me that this was entirely too much, and I made up my mind that a shorter incision would probably answer. I do not believe my incision was over 1¼ to 1½ inches in length. The stricture was not very wide but it was very hard and thick. Another thing I discovered was the remarkable friability of the structures. They had to be handled with great care. After making an incision I passed my finger down to prove what the condition was partly, and found that the tissues were quite soft and with this slight traction were liable to be torn. Also it had to be sutured with the greatest care, and I was disappointed in regard to the ease with which the operation could be performed. I found that when put to the test of practice, suturing the duodenum is not very easy. I congratulate myself that this operation was performed and the patient off the table with all dressings applied, in fifty-nine minutes. However, this I believe to be a longer time than the operation should require. We had spent some time in examining the gall bladder, inspecting the fluid withdrawn, etc., and I think if I were to proceed directly with the operation it could be accomplished in from twenty-five to thirty minutes. The operator has to work through a small aperture in placing his sutures, and it is altogether a difficult procedure. I do not see any necessity for making the incision is most cases longer than 1½ inches. The operation has been performed but a few times in this country.

---

## OPERATION FOR TUMOR OF PROSTATE GLAND.

### (CONTINUED REPORT).

Dr. W. O. Roberts: Under the head of continued reports I desire to mention one case reported to this society some time ago. The patient was a man from whom I had removed a tumor of the prostate gland that obstructed the passage of urine. This man had not passed any urine voluntarily, for a year. I removed the tumor and soon after the patient went home. At the time I reported the case I had a letter from a son of the patient, who is a physician, stating that his father was able to pass water naturally. Within the last three weeks I have received another letter in which he says there is no trouble whatever in emptying the bladder, and the patient has made a good recovery.

---

## CASE OF SIMPLE MENINGITIS.

Dr. J. A. Larrabee: I have recently had some cases that have been interesting to me. One in which I was especially interested, was a case of simple meningitis in a child about a year and three months old. The case was interesting because of the fact that we see so few cases of simple meningitis in comparison with those of

tubercular origin. Simply meningitis is oftener in my judgment due to injury or to disease of the middle ear. Inquiry in regard to this case showed that three weeks previous to any symptoms the child had been thrown from a buggy, receiving a blow on the head. An examination showed that the skin was adherent to the pericranium at one point. At the time of injury the history of the case was that the child turned perfectly blue, then white, then vomited several times, but the next morning felt perfectly well and no other symptoms developed until the end of 2½ weeks at which time unmistakable symptoms of meningitis developed. To-night the child is out of danger, simply by rest and treatment with bromide and a little calomel. The length of time between the fall and development of the pathognomonic symptoms of inflammation of the meninges, seems a little singular.

HEMIPLIGIA FOLLOWING INJURY.

Another case I would like to report and have some light thrown on and where a gentleman was relieved of a very serious condition, is as follows: Patient a male, fifty-five or fifty-six years of age; a well-to-do, well kept man, in the upper walks of life, and one who has attended to himself properly; has never had an illness; is of considerable size; of the apoplectic build, without the florid countenance, however. Three nights ago this gentleman fell to the floor with paralysis, as was reported over the telephone.

I saw the patient immediately and found him hemiplegic; no sensation whatever; no response to a blow on the foot or a pin in the hand; good intelligence, however. From this state of affairs my prognosis was very serious, and I gave very little encouragement as to the outcome of the case, thinking, of course, that the condition then existing was going to remain. I administered ten grains of calomel and ten grains of jalap. This had a decided effect and I found the next morning that he had hyper-catharsis. I saw him at two o'clock that day, at which time he could move his foot in bed. I used a pin on his hand and found that he had a little sensation; he said he knew I was doing something to him. Yesterday morning he was able to move both his hand and foot; to-night he can move them more freely, but says he does not feel quite natural. Now the question is, what was it? It certainly could not have been infarction of the vessels, and I am rather puzzled.

NOTE—Subsequent to the meeting I learned that this patient had sustained an injury in climbing over a fence—a strain of both arm and leg—only two days before the paralysis.

REPORT OF A CASE.

DR. T. H. STUCKY: A child, twenty-three months old, under my care died about three weeks ago, and, from the symptoms present I could see no cause for death. I report the case to show how marked were the pathological changes compared with the symptoms during life. I was sent for one morning to see this child; the mother said that during the night the baby had commenced vomiting, and a little diarrhœa. The tongue was flabby; temperature 100° F. I gave ⅛ grain of calomel and one grain of lacto-peptine, every hour until the character of the stools changed. The next morning I found the temperature 101° F. I gave it one grain of tannate of quinine every three hours. That afternoon I found temperature 102.5°F. Treatment continued. On my visit the next morning I found that the temperature was about normal, there was apparently no abdominal tenderness, limbs not flexed and the child had every appearance of being on the high road to recovery. The next day about two o'clock, I found the child in collapse, temperature 104,° marked opisthotanos. It died in about sixteen hours.

I will quote the result of the autopsy as made by Dr. Louis Frank:

*Body* of male child, well nourished.

*Head:* Dura mater adherent to skull; at vertex these adhesions are so dense that it is impossible to separate the dura from the bone, the pia is slightly distended, a clear fluid escaping when pia is cut through. Along the vertex there is some cloudiness; milky appearance along the larger vessels, and in this a few whitish tubercles are found scattered about near the fissure of Sylvius and at vertex. The layers in the Sylvian fissure are adherent. Lateral ventricles contain about ½ ounce fluid, clear. Ependyma somewhat cloudy.

*Abdomen:* Distended; on median section pus and fibrinous flakes appear. Cavity

contains pus—about eight or ten ounces—which is mostly, however, in the pelvis. Intestines agglutinated but the coils can be separated. The vermiform is found passing down into the pelvis, and is held there by adhesions to the sigmoid and rectum. The sigmoid lies somewhat over it. After separating carefully the rather firm adhesions, the appendix is found to be about three inches long, with a mesentery to its proximal one-half. The appendix after ligation, is taken out and opened. It presents a small perforation at its extremity; contains no feces, seeds or other foreign body; is filled with a thick, mucous-like substance."

In connection with this report of the autopsy, I want to state that at no time during the child's sickness was there any abdominal distension; the bowel seemed to have been restored to its natural condition; there was no history of chill and no explanation of the cerebral condition. Careful inquiry reveals no history of tubercular trouble in the family on either side, and no history of specific trouble on the father's side; that the only injury the child had ever sustained was received about eight months before, when he fell out of a chair on to the top of his head. They did not call a physician as they thought he was all right. At nine o'clock in the morning, or three hours before I was called hurriedly by telephone, he was sitting on the floor playing with some blocks. I met his father that morning and asked how the little boy was and he replied that he was all right. That night he died. The case is of interest to me from the fact that the symptoms existing were out of all proportion to the revelations made at the autospy.

### DISCUSSION.

Dr. J. A. Larrabee: The case is certainly one of interest, and one upon which little light can be thrown, especially as there is no history of either a specific or a tuberculous nature. If the injury had any thing to do with the adhesion of the dura mater and condition of the brain found, then according to all pathology the child should have had epilepsy or seizures of some kind. In regard to the pus found in the abdomen, while peritonitis is not often overlooked or mistaken in the adult, I have seen children with peritonitis—have had it occur in my practice, where symptoms were not present to such an extent as to attract attention, or sufficiently marked to be separable from ordinary colic or gastric attacks, and diseases of a milder character. But from fact that there was a perforated appendix, it would seem that in this case the mischief had been going on for a considerable time; this is also evident from the mal-position of the appendix and agglutination of the intestine. It is a very anomalous case.

---

### PAPILLOMA OF LARYNX.

Dr. J. M. Ray: I have had under observation for several days a case of papilloma of the larynx. A woman thirty-eight years of age, consulted me for loss of voice and gave this history: Three years ago she suffered in a similar way, having a cough and loss of voice; she could make a tone loud enough to be heard, but it was only with an effort that she was able to do so. One day she was seized with a severe attack of coughing and spit up what on investigation proved to be a lump of flesh as large as a bean. Immediately she could talk with ease and had no further trouble until recently, when she began to get hoarse with considerable cough. This increased until she decided to consult a specialist.

When I saw her a week ago, she could talk in an ordinary tone but with a little huskiness. She said she could not call the children about the house and had not been able to do so for several weeks. Upon looking into her throat I found in the larynx, occuping the inter-arytenoid space, a papilloma about the size of a bean and with a broad base. I told her it would have to be removed. To-day I clipped off a piece, but did not succeed in removing all, as the throat was sensitive and I decided to make another attempt later. The interesting feature of the case is that the patient had the same trouble three years ago, the growth evidently becoming pedunculated, and in coughing it was broken loose and spit up. Cases of this kind occasionally occur in children, papilloma of the larynx become detached or disappear, but this is the first case I have ever seen in adult life.

# CORRESPONDENCE.

## CONSUMPTION OF THE LUNGS IS NOT TO BE COMPARED WITH LEPROSY.

EDITOR OF M. AND S. REPORTER.

Having devoted years to the study of the life history of germs found in tissues affected with Tuberculosis (consumption), and also having had practical experience with Leprosy, I take the liberty of offering a few words of consolation to those suffering with consumption of the lungs, who have been unduly alarmed by the words of enthusiasts who have, I have no doubt, unintentionally led the lay mind to class the contagiousness of consumption of the lungs with the popular impression of Leprosy; while it is largely based upon the horror with which the ancients looked upon the malady. Leprosy of the early ages was in all probability much more contagious under the habits of the patriarchs than it is with those living in the easy, comfortable and peaceful ways of Philadelphians.

From the facts, however, that Bates has found the bacilli of Leprosy on the hair follicles, and I in the spittle ejected from between the ulcerated lips of a leper while talking, and, also in uncountable numbers from the surface of the tongue of the same individual; while others have demonstrated their presence in the blood, we can readily understand why the people in the time of Moses were warned to burn the clothes of the leper, claiming that the garment worn by one was fretting leprosy and further that "the house shall be scraped off without around about, and they shall pour out the dust that they scrape off without the city, into an unclean place, etc." If the bacillus of Leprosy is the infecting cause, the contagion may be spread from more uncontrollable sources than is the poison of consumption of the lungs, viz: from the blood, the hair that falls out, the spittle from the mouth and from leprous tumors. These numerous sources make it next to impossible to live with a leper, without running a risk of becoming infected with the much dreaded malady, providing those exposed are predisposed to the contagion. The conditions, however, that render one susceptable are not understood by the medical profession. If the hairs from the body contain the poison of leprosy, isolation is almost necessary, and, in this country, but a few, yea, a very few families would be made unhappy by the enforcement of such a police regulation. As a matter of fact, the lepers I have talked with seemed to prefer to be alone; they seemed to appreciate their uncleanliness. There is, however, a very wide gap between coming in contact with the bacilli of consumption of the lungs and those of leprosy, under moderate care. This is on account of the number and character of the sources from which the bacilli leave the blood of a leper. The principal factor in conveying the bacilli of consumption of the lungs is the sputum, that unlike the hair of the leper can be caught and the bacilli therein absolutely destroyed.

Again, kissing by the consumptive can easily be avoided; the tooth brush can be cleansed by destroying the bacilli therein; the utensils used in eating can also be made clean, and so can the communion cup; otherwise, those predisposed to consumption of the lungs may fall victims to the poison from an infected person.

The Board of Health would certainly do well by protecting public places, while it is a grave matter to trespass upon the sacred privacy of nearly one-seventh of our people—public officers should not be permitted to enter the homes of such a large proportion of our people. It would destroy their privacy and lessen their finer feelings of modesty. They must not be treated as cattle, but as refined human beings. Should a public inspector be privileged to enter the house of a consumptive it would not avail us much, for he certainly would not be permitted to rush into the private apartments of a lady without awaiting her convenience, and if he was required to await the convenience of the sick, those disposed to be criminally careless would certainly dispose of any trace of guilt before he entered the compartment.

Why is not the medical advisor as trustworthy as the inspector appointed by the Board of Health? If so, his opportunities for detecting hygienic neglect are much greater than those of the city officer appointed for that purpose. This being the case, one might believe it well to have a law providing for the enforcement of regularly formulated sanitary precautions, upon the medical attendants reporting the neglect of any one suffering with consumption of the lungs or throat to carry out the rules of the Board of Health.

Not to be understood as opposing, in the least, the important object of the County Medical Society, I do wish to relieve the public mind of the impression that the loathsome condition called leprosy is like consumption of the lungs, in either cause or effect.

The leper is most often a great sufferer and a hideous object to behold, as well as being an almost useless member of society. The consumptive, on the other hand, up to the very advanced stage of the malady, is comparatively happy, and is, most certainly, a very useful member of society.

One of the true sayings of our illustrious Dr. S. Weir Mitchell is, that a person suffering with a disease below the diaphram never dies a heroic death. While this is very general in its application, those affected with consumption of the lungs are generally extremely happy, and are often very attractive in their personal appearance. They, as I have already said, comprise at least one-seventh of our population, the liberties of whom must not be trespassed upon one particle more than is absolutely necessary for the good of themselves and their fellow citizens.

Samuel G. Dixon, M. D.
The Academy of Natural Sciences of Philadelphia.

## IRRIGATION OF BLADDER.

In preparing for irrigation of the bladder, the first step is to scald out a small pitcher. In this the antiseptic powder is dissolved in a few ounces of boiling water. While waiting for perfect solution, a pint and a half of boiling water should be poured into the fountain syringe and allowed to remain until the syringe is needed. The catheter, which has been kept in a bottle of 1:1000 bichloride solution, is removed to a small basin containing boiling water. The antiseptic solution can now be reduced in temperature by the addition of cool, sterilized water taken from the cotton-plugged bottle already mentioned. The prepared solution is now poured into the fountain syringe, all air is expelled, and the cut off screwed down. Meanwhile, the nurse has cleansed the external genitals of the patient with a 1:2000 bichloride solution. There remains only to pass the catheter and connect it with the tube of the syringe. Taking the catheter from the hot water with fingers disinfected in an antiseptic solution, bichloride glycerin is poured over two inches of the end as a lubricant, and the instrument, in a good light, is passed instantly into the bladder.

If the bladder is full, considerable urine must be allowed to escape to make room for the antiseptic solution. If there is little urine, there is danger in allowing it all to run out and permitting germ-laden air to be introduced through the catheter. The only convenient means of expelling the air from the catheter, when this instrument is first introduced into the bladder, is to allow a small stream of urine to pass outward through it. Before the catheter is connected with the syringe tube, all air must have been likewise expelled from the latter by allowing a column of the antiseptic solution to pass through. At first a gentle stream is turned on. The force is governed by the elevation of the reservoir and by the screw cut-off. The importance of injecting slowly can not be too strongly emphasized.

When the patient begins to feel a sense of slight distention the tube and catheter are disconnected. While the operator cuts off the stream from the syringe with his right fingers, with his left he guides the stream from the catheter into a quart bowl placed between the patient's legs. The operation of siphoning must not be carried to the extent of absolutely emptying the bladder. A little fluid should be left in to prevent the admission of air and to keep the bladder-walls from collapsing and causing spasm. It is best to leave at least an ounce of the antiseptic solution in the bladder after the last siphoning.—*M.B.*

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, NOVEMBER 11, 1893.

## EDITORIAL.

### IMMUNITY AND TETANUS.

There is, perhaps, no disease with which investigators have worked to obtain practical results in the way of treatment which has given quite as much satisfaction and encouragement so tetanus. The hoped-for results from tuberculin have not as yet been realized, and the prevention or cure of diphtheria by means of chemical substances isolated from cultures of the specific organism, or with the blood serum from animals rendered refractive to the disease, has not been satisfactorily demonstrated, although many promises have been given by preliminary observations.

With tetanus, however, the results are more encouraging. In a previous number of THE REPORTER were given the details in the successful treatment of a few cases of tetanus with the blood serum from immunized animals. The number of cases which, thus far, have been reported is about twenty—eleven of which recovered. In those that were not successful the disease ran a very rapid course and the treatment was not begun until the disease had become well advanced. The course of the disease lasted only from two to six days in the fatal cases. Even in those cases there was thought to be evident improvement upon the commencement of the treatment. As the fatality of tetanus is about eighty-five per cent., the conclusion which can be drawn from the cases reported is certainly very encouraging.

Two extremely interesting cases are given:

(1.) Taruffi reports (*Centralblatt f. Bacteriologie u. Parasitenkunde* 1892, p. 625) the following case: A peasant, aged seventy-four years, suffered a lacerated and contused wound of the little finger of the right hand. The wound was not dressed and suppuration followed. Ten days after the injury symptoms of tetanus developed. These increased in severity and two days later Tizzoni examined the case and injected twenty-five centimeters of antitoxin. This was followed by improvement and an increase in quantity of urine eliminated. The finger was ampu-

tated and virulent tetanus bacilli were cultivated from the wound. The tetanic symptoms gradually disappeared under the influence of repeated injections of antitoxin. On the eleventh day after beginning the injections, the patient was pronounced well. The total quantity of the antitoxin that was given was 150 grammes. It was further noticed that the urine was toxic before the treatment but not afterwards (third day), and blood serum from the patient did not induce tetanous symptoms in a rat, on the second day after treatment. These observations were considered as pointing to the neutralizing power on the part of the antitoxin and the toxin of the disease.

(2.) The second case reported by Casali (*Ibid*, 1892, p. 59), was a woman who injured her foot while working in a field. She paid little attention to it and on the following day was unable to walk. She consulted Casali who dressed the wound and ordered rest, which order was not obeyed. There followed, in a few days, swelling of the glands and suppuration of the wound with symptoms of septic infection. A few days later symptoms of tetanus appeared. The wound was examined bacteriologically and tetanus bacilli together with streptococci septicus were found. Antiseptic dressing of the wound was carried out and antitoxin treatment for tetanus begun. The tetanus symptoms disappeared after the sixth injection, but the septic trouble continued. Here there was a case of mixed infection, with a specific cure for one while the other remained unaffected by the treatment. This is especially interesting as it shows that the antotoxin could still produce its reaction even in the presence of the toxines that were produced in the blood by the septic infection.

In these cases we have a most admirable illustration of the "blood serum therapy," although others, not mentioned here, illustrate it even more fully. The accumulation of such a large number of cases with such favorable results, suggests the importance of having an institution for the treatment of tetanus, or at least for the purpose of preparing antitoxin, in America.

## TRANSLATIONS.

### SOME POINTS IN THE TREATMENT OF GASTRIC ULCERS.

The author, Dr. W. Fleiner, regards subnitrate of Bismuth as one of the best therapeutic agents given in large doses, and presents the indications for its use in the following manner: 10 to 20 parts bismuth subnitrate to 200 parts of water, in cases where simple washing with the stomach tube is not followed with the desired results, is given through the tube. It is generally useful in chronic cases of gastric ulcer, ulcerated carcinoma and hemorrhagic erosions, motor and secretory irritability. It is a specific agent in duodenal ulcers. These injections are first used daily, later every other day, and still later every third day until the case is cured.

After the use of 300 to 400 grms, no poisonous effects were observed. In cases where constipation appears enemas of oil were successfully used to combat it.

In the second group of cases bismuth was given in large doses 10, bismuth subnitrate, in a glass of lukewarm water to be stirred thoroughly and drank before breakfast. This was used in cases of gastric and duodenal ulcers in which the stomach tube was contraindicated. It was also useful in hemorrhages of the stomach.

Bismuth is contraindicated in cases where there is a decrease of acid secretions, the only exceptions being in hemorragic erosions and ulcerating tumors.—(*Müch. Med. Woch. 1893.*)

## CLINICAL AND ETIOLOGICAL OBSERVATIONS OF PSORIASIS.*

The author, Dr. Nielsen, having studied 927 cases during 25 years at Prof. Haslund's Clinic, presents some points of interest. Localization: the palmer and planter surfaces are more frequently attacked than is generally supposed (19 per cent.); punctated affections of the nails (10 per cent.); the extremities come next in frequency.

As an average, an attack, under the treatment of large doses of iodide of potassium (50 gm. per day), lasted in 27 adults, 38.7 days; in 13 children 61.9 days. In cases in which arsenic was used internally with external medications, the attack lasted, as a rule, 52.3 days among nine children. It is probable that the arsenical treatment, given in increasing doses, will produce the same effect as the iodide of potassium.

The disease runs a thoroughly atypical course, lasting in some cases throughout life, having its remissions and exacerbations.

There were forty-nine cases in which remissions occurred at intervals of from 1 to five years; in ten, 5 to 10 years; in eight, 10 to 32 years. Generally the disease has no tendency to increase with the age of the patient, even though treatment be left out of the question. Chronic alcoholism or rheumatic joint affections frequently increase the severity of the attack, while intercurrent diseases accompanied by marked changes in nutrition, often act as a curative measure. Exacerbations frequently occur in the spring or fall. The disease occurs oftener in the male than in the female (3:1); is most frequently observed between the ages of 5 to 15, (in about 44 per cent); and after the age of fifty is found in about 2.7 per cent.

In 306 patients there was a distinct hereditary history; 29 per cent. showing that the disease existed in the immediate family; in 15 per cent. there was a history of a recent introduction. There is no etiological proof, however, that heredity should be considered of greater importance than contagion.

In isolated cases, psoriasis followed an attack of measles, scarlet and typhus fever, erysipelas and pleuritis, while in chronic affections (carcinoma, diabetes, etc.) it has often disappeared.

Patients suffering from other skin affections (prurigo, ichthyosis, eczema, etc.) are not exempt from psoriasis. Pregnancy in some instances has acted as a cure.

Statistics collected from the larger cities of Europe show that there was in 15,376 cases of skin affections 6.5 per cent. psoriasis, and in America 58,617 cases showed only a percentage of 3.28 (J. White). — *Schmidts Jahrb.* No. 8., 1893.

## A CASE OF PSEUDO HERMAPHRODISM.*

From the patient, aged 21 years, in whom there had been a cessation of menses for 4 years, the author, H. Fehling, removed a myo-sarcoma of the left ovary, weighing 5 pounds. The following congenital deformities were observed by careful examination, external and internal, regarding sex. At the location where the clitoris should have been was an appendage, 5 cm. in length, with the thickness of a thumb, at its end resembling the head of a penis, with an illy defined prepuce; behind the base of this organ an opening was found which corresponded to the vagina in the female, 8 cm. in depth and with some traces of a hymen.

The left labium was poorly developed but normally formed; the right presented a rounded, sack-like appearance similar to the scrotum. A small oval, tender body was found in it. The operation revealed an infantile uterus. The right tube and ovary had descended through the inguinal canal into the right labia.—*Arch. J. Gyn.* xlii, –92.

* Translated for The Medical and Surgical Reporter by Marie B. Werner, M. D.

### INFANTILE ECLAMPSIA.

A child, aged 6 months, having a reducible inguinal hernia, was suddenly attacked by severe eclamptic convulsions. The author, G. Feurer, noticed that each attack preceded a bowel movement or an escape of flatus. The child died during one of these attacks. Autopsy disclosed that the vermiform appendix, 10 cm. in length, had slipped through the inguinal canal and was adherent to the testicle.

In a second case—a child aged five months, also having a reducible inguinal hernia,—suffering from eclamptic attacks, the author, profiting by the lesson of the first case, proceeded at once to perform a radical operation, with the most happy results. The patient made a rapid and good recovery, the eclamptic attacks ceasing immediately after the operation. The hernial sac contained the coecum and vermiform appendix, the latter being firmly attached to the walls of the sac.—*Corres. Bl. f. Schweizer Arzte 1893.*

## ABSTRACTS.

### THERAPEUTIC EFFECT OF HIGH ALTITUDE.

C. Theodore Williams, in a lecture delivered before the Royal College of Physicians, London, states that his studies of the effect of high altitudes on phthisis warranted the following conclusions:

1. Enlargement of the thorax takes place unless opposed by the growth of fibrosis, or by extensive pleuritic adhesions.

2. Males and females seem to do equally well, and profit most between the ages of twenty and thirty, males over thirty and females under twenty benefiting least.

3. The climate is specially beneficial in hemorrhagic cases and in hereditary cases, and appears in the latter class to exercise a distinctly counteracting influence on the development of phthisis.

4. It is most effective in cases of recent date, though of utility of those of long standing, and to insure its full benefit at least six months', and in many cases two years', stay is desirable.

5. With regard to the actual results of the climate, it undoubtedly produces great improvement in 75 per cent. of cases of phthisis generally, and in 43 per cent. it causes more or less complete arrest of the tubercular process.

Its beneficial influence is best shown on tuberculous consolidation, where improvement may be looked for in 87 per cent., and arrest in 57 per cent. Arrest takes place in 16 per cent. of the patients with excavations, and great improvement in 55 per cent. High altitudes also prove beneficial in:

1. Imperfect thoracic and pulmonary development.

2. Chronic pneumonia and bronchiectasis.

3. Chronic pleurisy, where the lung has not expanded after removal of the effusion.

4. Acute phthisis of all kinds, and especially where there is great irritability of the nervous system.

5. Phthisis with pyrexia, and in pyrexial cases generally.

6. Emphysema.

7. Chronic bronchitis and bronchiectasis.

8. Diseases of the heart and great vessels, except functional ones; diseases of the liver and kidneys, including all forms of albuminuria (Andrew Clark.)

9. Diseases of the brain and spinal cord, and conditions of hypersensibility of the nervous system.

10. Anemia.

11. In patients of advanced age or too feeble to take exercise.—*Brit. Med. Jour.*

* Read before the Freie Vereinigung der Chirug., Berlin, 1893, and translated by M. B. Werner, M. D.

## THE COUNTRY DOCTOR.

Prof. Wm. Keiller, in his address to the matriculants of the Texas Medical College, in Galveston, on the opening day of the present session, drew the following beautiful picture of the country doctor.

Prof. Keiller said: "Now in closing I wish to present to you a picture of the goal for which you are striving, a little glimpse of one of the noblest lives that men lead on earth.

"In the winter of 1890, there appeared in the Royal Academy Exhibition in London, a picture which attracted large crowds of warm admirers, and stirred many of them to their heart's core. Luke Fildes had been asked by a patron to paint a picture illustrative of English life, and he chose "The Doctor" as his subject, and painted to the life the ideal representative of the most humane of professions. No prosperous, wealthy specialist is this hero of the medical world. The first glance at the man reveals the general practitioner, the hard-worked country doctor. The only daughter of a humble farmer, a wee, curly-haired lassie of two or three, is sick, well nigh unto death. It is no long, wasting disorder—she is too plump for that; but the crisis of an acute malady. The next few hours will probably decide her fate. It is evening, and the doctor has seen her in the morning, and now, tired by a long round of visits, he has called again; and his energies, fatigued as he drove along in his buggy, are again called into full activity by the exigencies of the case before him. Poor wee pet! She is very low. Her pulse is rapid and feeble, her respiration quick and shallow; but, if her heart can be kept up a little longer, she may get a little sleep and ultimately pull through. Our doctor has with his own hands given her her medicine, and now sits watching its effect. Already she is soothed, her pulse is a little slower and firmer, her respiration less hurried, and she has dropped into a brief doze.

"And while she sleeps let us look at the doctor. He is the central figure of the painting, the center of interest even to the stricken father and mother, because in his hands is the life of their first-born. A man of strong and massive build, about forty, and therefore in the zenith of his mental vigor, with fifteen to twenty years' experience to mature his judgment; no dude, but well dressed as self-respect demands of all men of well balanced minds; the whole man reveals the well-to-do country practitioner. And his face? Genial, thoughtful, and above all things reliable and strong. There is no weakness there.

"It is late, and he is tired, but there is no languor in his attitude; he has forgotten all the world,—wife, children, the cosy supper waiting for him for an hour or more, the father and mother of the child, all are forgotten but the patient and his science. He is not absorbed over an interesting case which will be worth reporting at the local society; he is face to face with a problem of life and death. No debasing thought of a big fee (I am almost ashamed in the face of such a scene to mention the word)—I say, no thought of his fee mars the current of his calculations. No big fee can come out of that small cottage; but a little laughing face that was the sweetest sunbeam of the young couple's hearth may shine again or set to-night, and the doctor's skill may decide the matter.

"In the background the young mother, wearied with watching, has yielded her place to the man in whom, next to God, her trust is placed; and has laid her head upon the table, half in despair, half in unuttered prayer. Her husband stands beside her, his hand, with a subtle sympathy that she alone can fully understand, on his wife's shoulder; a touch that means hope for the best, sympathy and strength for the worst, his face expressive of the calmer way in which strong men meet life's worst vicissitudes.

"Gentlemen, it is well that in commencing a new course of life each man should have an ideal, and should keep his ideal ever before his mind. And I would hold up before you as a high ideal this picture of the country practitioner. Few of you will ever have the opportunity to become great specialists; but all of you may become most excellent men and good physicians, and lead lives which shall call down on your heads the blessings of a grateful people. The man whom our artist has chosen is a student every inch of him; a true man of science, but his science is a means to relieve suffering hu-

manity. He is no money grabber; no dispenser of drugs at so much a bottle; no smooth, honey-tongued ladies' doctor with half hours to spare listening in scented, half-lit rooms and cushioned lounges to a languid account of imaginary ailments. He is no brilliant specialist, who has, by hard, up-hill work and much self-denial it may be, or by some lucky stroke of fortune, reached that pinnacle of success where life is easy, leisure frequent, successes brilliant, and fees often princely. He is strong; strong because of his knowledge, because of the hard, honest work of his student days, because though he may not have carried off honors he has determined to understand everything he has studied and make it his own; strong because since his college days he has remained always a zealous student; strong because it is his nature to be so. Such a physician must be reliable. His word must be slowly given, but when given as good as fulfilled; his word must be his bond; his tongue and his whole life must speak the truth. Our ideal physician must be benevolent—generous even to a fault, but just also. No warm-hearted waster of his goods and energies on all and sundry, but ready ever to err on the side of generosity and great-heartedness where there shall appear a fitting object for his compassion.

"He must be unselfish. No life grates more on the selfish than the physician's. He, more constantly than any other man, is called on to sacrifice self, health, wife and children, home comforts and home duties. It is not on the specialist that all this falls most heavily; it is on the general practitioner.

"In short, gentlemen, the life before you is one of labor from the beginning. If you wish to make fortunes do not study medicine. Patients you may have in plenty, and your pockets all the time be very empty, aye, even gratitude may be denied you. But you have chosen a profession than which none is more full of scientific interest, no study is more fascinating, no life gives more constant opportunity for the highest moral culture. And now and then you will get a handshake from a husband or father, a look from a wife or mother, that will make you feel that life is worth living after all, and you had rather be a doctor than anything else on earth."—*Texas Med. Jour.*

## THE INFLUENCE OF TREATMENT OF A SYPHILITIC MOTHER, ESPECIALLY DURING PREGNANCY, UPON THE HEALTH OF THE INFANT.

Etienne (*Annales de Gyn.*, April, 1892; *Am. Journal of Obstet.*, February, 1893) draws the following conclusions from the study of thirty-two cases of pregnancy in syphilitic women:

1. The fœtal mortality, in cases in which the mother has never been treated, is enormous, reaching 95.5 per cent. If treatment be applied throughout pregnancy, we may hope to obtain almost complete immunity from this infant mortality.

2. Syphilis attacks the fœtus especially during the fifth, sixth and seventh months of intrauterine pregnancy.

3. Paternal syphilis is less injurious to the fœtus than maternal syphilis.

4. The prognosis differs according to the stage of pregnancy when the mother becomes contaminated.

(*a*) If infection occurs during the first three months and is not treated, the mortality during the first few days after delivery reaches one hundred per cent.

(*b*) The prognosis is a trifle better, if infection occurs during the fourth and fifth months.

(*c*) In one case of infection at the eighth month, the child lived and was apparently healthy; in a second similar case the child was in good condition at birth, but developed symptoms of syphilis later.

(*d*) Whenever suitable treatment was administered, the mortality was *nil.*

5. In no case was any unfavorable results met with from internal medication during pregnancy.—*Boston Med. and Surg. Jour.*

## THE PATHOLOGY OF LAZINESS.

Many persons are unjustly compelled to bear the reproach of laziness, when their indisposition to exertion really has a physical basis, and depends much upon some grave disturbance of nutrition. Such cases deserve our sympathy, instead of the contempt which is unsparingly metted out to them by their more robust associates. Women, whose instincts are often remarkably correct, understand this, and when a child is unusually quiet and prefers to sit still, instead of joining its companions in play, the mother's fears are aroused; she thinks at once that something is wrong, and that the child is going to be sick, or is actually suffering from some obscure internal disorder, possibly hip-joint or spinal disease. This explanation may apply in adults as well as in children. Some years ago, a clergyman, who had been very active in church work, was noticed to gradually give up one duty after another, and to show marked disclination to perform any work requiring much exertion of body or mind. He was generally thought to be losing his interest and getting indolent. Indeed, he feared himself that this was the case, and it gave him much mental distress and spiritual disquietude. He afterwards came under the observation of a physician, who found that he was suffering from Bright's disease, from which he subsequently died. He was especially regretted by those who had hastily and ignorantly condemned him for what was assured to be a fault, but which, in reality, was due to grave disturbance of nutrition from the approaches of an insidious organic disease. Victims of chronic malarial poisoning afford typical illustrations of laziness, although clearly suffering with bodily disorder. Who can estimate the amount of physical disability and apparent indolence which is directly due to dyspepsia and chronic indigestion? Rheumatism and the muscular pains of lithæmia, locomotor ataxia, and its nerve-counterfeits, incipient brain disease, and arterial degeneration, are all potent factors in producing indolent habits of body, while phthisis, pernicious anæmia, and neurasthenia have physical weakness as a prominent and early symptom. A dislike for study in a child may often be traced to errors of refraction which are remediable by proper adjusted lenses.

Before pronouncing, therefore, a verdict of moral fault, and condemning those who are conspiciously deficient in energy, and whose powers of work are notably below the average, it would be well to stop and inquire whether they are not laboring under physical disability instead of indolence. In such cases it may be found that better results will be obtained by placing them under the charge of a physician than under an instructor in morals. The decision between the hospital and work-house is often a difficult one to make for those wrecks of humanity, the physical degenerates, who become tramps because they have a moral and physical aversion to work. In a strictly analogous manner, in higher walks of life, when a physician prescribes physical exercise for patients who obviously require it, he often finds his instructions disobeyed simply because the physical disability of the patient is the real reason for his condition; for if he had the power to follow the prescription he would not need his advice. It appears, indeed, that, in certain instances, laziness may be a conservative effort of nature; and, as a symptom, will be estimated at its proper value by the intelligent physician.—*Food.*

---

A Foreign Body in the Ear for Thirty-nine Years.—A correspondent of the *Medical News* reports the case of a patient who complained of occasional pain in the left ear since childhood. Hearing was almost lost and the canal was filled with a hard substance. With some difficulty a large white bean was removed, with the immediate return of hearing. On questioning the patient it appeared probable that the bean had been in the ear for thirty-nine years.

---

### To Clean Stove Pipe of Soot.

This can be done without taking down the pipe and imperilling the combination. Take about two pounds of strip zinc, and when you have a large bed of coals put in your zinc and open the draught in the chimney—if this is done every three or four days the pipes will be effectually cleaned.

## THE DISORDERS OF THE NERVOUS SYSTEM ASSOCIATED WITH THE CHANGE OF LIFE.

Dr. Gustavus Eliot in concluding this article offers the following propositions:

1. At the time of life when the menopause occurs the various organs of a woman's body are likely to be in a state of depression as regards either their nutrition or functional activity, so that the normal equilibrium of health action may be easily disturbed, and abnormal action, the manifestation of disordered function, may be inaugurated and perpetuated.

2. The cessation of menstruation is an event of great physiological importance, and is perfectly competent to produce grave disturbances of the nervous system, if any predisposition to them already exists.

3. The more common disorders of the nervous system occurring under these circumstances are functional in character, and are associated with disturbances of functions of other organs, and especially of the digestive, circulatory, and hematopoetic systems.

4. In their treatment, attention should first be paid to improving the general nutrition of all the tissues of the body, and restoring each organ to its normal activity.

5. If, after all other organs have resumed the proper performance of their functions, symptoms referable to a disordered condition of the nervous system still persist, recourse must be had to remedies which act directly upon the nervous system, either by improving its nutrition or by modifying and regulating its action.

## REFORM FEATURES OF THE GOTHENBURG SYSTEM OF LIQUOR TRAFFIC.

One of the most interesting provisions of the by-laws is that the manager of a bar saloon must always keep on hand both cold and hot prepared food. He conducts the sale of viands as well as coffee, tea, cocoa, mineral waters and cigars on his own account, receiving whatever profits may be made from his transactions. It is expressly forbidden to sell intoxicating drinks to a person already under the influence of liquor, or to a minor.

The idea of the reform at the outset was to take care of the working people especially, so everything that has been done by the company has had this end principally in view. Four eating houses, where drams were sold only with food, were established. These places are well equipped with steam cooking apparatus, and aim to offset the attractions of drink by the presentation of cheap and well cooked food. An attempt was made by the company to compel on Friday evenings, when wages are always paid in Sweden, the purchase of a portion of food with every glass of liquor asked for. The workingmen, however, thought this to be too great an interference with their individual liberty, and the attempt was soon abandoned as a failure. The Gothenburg Company has also shown its regard for reform by the establishment of five reading rooms in which no intoxicating drinks are allowed to be sold. The annual cost of maintaining these institutions is something over three thousand dollars, and it is interesting to know that a record of attendance showed 217,207 visits to its reading rooms during the year ending September 20, 1892.

THREE CLASSES.—Charles Kingsley, writing to some young friends who were addicted to gambling says: "My dear boys, the human race may, for all practical purposes, be divided into three parts: (1) Honest men, who intend to do right, and do it; (2) knaves who intend to do wrong, and do it; (3) fools, who aim to do whichever is pleasanter. The latter class may be subdivided thus: (1) Black fools, who would rather do wrong, but dare not *unless with the crowd*; (2) white fools, who would rather do right, but lack courage *unless it is in the fashion.*

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES

for October. Dr. William Osler contributes a paper on

**Sporadic Cretinism in America.**

The author states that there is no essential difference between those cases occuring in large numbers in goiterous districts and the sporadic cases. The term should be limited accurately to a form of idiocy associated with changes in or absence of the thyroid gland. The important factor is the loss of the function of the thyroid gland, whether this results from congenital defect, progressive atrophy, or coarse changes which gradually annul its function.

The author discusses congenital cretinism, and that developing in early childhood, as well as endemic and sporadic cretinism. The article deals with the subject most minutely, both in regard to the pathology of the disease and the historical literature on the subject. The interest in the subject is at present a very practical one, inasmuch as the observations on the beneficial effects of thyroid feeding have been shown in several cases, particularly in those seen within the first three or four years of life. The author has at present two cases under treatment, but both for such a short time that it is impossible to say as to the changes in the condition.

The paper also includes the report of a case of operative myxœdema following the removal of the thyroid in a patient eighteen years of age.

Dr. Francis H. Williams discusses

**Diphtheria and Other Membranous Affections of the Throat.**

He emphasizes particularly the following points:

1. The necessity of cultures as a means of early diagnosis.
2. The coincidence of diphtheria and other diseases.
3. The bacteriological examination of all patients ill with scarlet fever, typhoid fever, measles or other disease, who have membranous throats.
4. The bacteriological examination of specimens from the throats of all diphtheria patients before isolation is ended.
5. Seven and one-half (known at present in the United States as fifteen) volume solutions of hydrogen peroxide are weak germicides.
6. The advantages of strong hydrogen peroxide solutions, locally, in diphtheria. The substitution of harmless and more efficient for harmful or inefficient local treatment.
7. The importance of frequent, early local applications.

Dr. W. T. Councilman contributes a paper on

**The Pathology and Diagnosis of Diphtheria.**

He regards only those pseudo-membranous inflammations as belonging to diphtheria in which the Klebs-Lœffler bacillus is found. When it is not present, no matter what the extent and the character of the local lesions, or the severity of the symptoms, the disease is not diphtheria. He also discusses the pseudo-membranous inflammations of the larynx accompanying typhoid fever, and thinks they are more common than is usually supposed but are generally overlooked owing to the hebetude of the patient preventing any of the symptoms of the throat affection from appearing. While it is not proven that these inflammations are due to the Klebs-Lœffler bacillus, yet there is one case in which it is positive that the organism was found. In his experience the membrane is more apt to be found at the beginning of the œsophagus on the posterior wall of the pharynx than in any other place. Diphtheria bacilli have been found by the author in one case of inflammation of the middle ear following diphtheria, and in two cases of inflammation of the middle ear following measles. In the two cases of measles there was no affection of the throat at the same time and the author is inclined to view the occurrence as one of accidental wound infection.

In regard to those cases reported in which the Klebs-Lœffler bacillus was said to be found without any pseudo-membranous deposit in the throat, the author is inclined to believe that the whole respiratory tract was not examined for lesions.

The author thinks there is no doubt that the danger in diphtheria lies chiefly in the absorption of the virus which is produced locally, and that this does not take place with anything like the same readiness in adults as in children. This is probably due to the more delicate tissues of the child, its greater vulnerability and possibly a greater facility of absorption. It is very probable, however, that just as there are different degrees of susceptibility of the mucous membrane to the local action of the bacilli, so there are also differences in susceptibility to this systemic poisoning.

The staining which he has found uniformly best suited to the detection of the bacillus is the Loeffler solution of methylene-blue, consisting of methylene-blue dissolved in a weak solution of caustic potash. He states as a general rule that the more abundant the various organisms which are found, the less likelihood of the case being one of diphtheria. In his examinations he relies chiefly on the methods of culture.

Dr. J. M. Bannister discusses "Rifle Practice in its Relations to Eye-Strain." The author finds that the present color of the target is productive of great eye-strain and suggests that the color be changed and the element of glare reduced to a minimum.

This can easily be effected by making the body of the target black and the bulls-eye and rings buff. He also suggests that, as some recumbent posture seems essential to good long-range shooting, the prone position be made the sole regulation recumbent position, and that the back and side postures be excluded.

Dr. Emil Mayer reports a case of "Congenital Strictures of the Oesophagus." In the treatment, an œsophageal bougie of full size, No. 18 of the English scale, was passed under ether into the stomach with immediate relief. Previously the child had been accustomed to eat and try to swallow as she lay on her back with her head far extended. The obstruction in this case was, in all probability, due to a membranous band almost occluding the œsophagus in its lower portion. The child has been under observation for one year without any trouble.

Dr. James E. Newcomb contributes a paper on

**The Occurrence of Hemorrhage After Operation for the Removal of Adenoid Tissues from the Naso-Pharangeal Vault,**

reporting a fatal case. He thinks that patients from whom adenoid tissue is removed should be kept under careful observation for at least twenty-four hours. No single instrument is the ideal one for every case. Unless one single application of the curette will suffice to clean out the pharyngeal vault the writer inclines to the use of an anæsthetic. He prefers ether carried to the primary degree, and the forceps, either the Gradle instrument or a modification thereof, and supplemented frequently by the use of the curette and finger-nail.

Dr. Earnest E. Maddox reports "A Case of Poisoning by a Belladonna Plaster." The plaster in question was manufactured by a firm which prides itself on the excellency of its belladonna plasters, and which exhibits the results of tests to show how much more belladonna they contain than the officinal plasters. The case recorded shows that there is a limit to excellency of this kind, and that there is need of caution not to carry it too far.

The remaining paper is the report, by Dr. Walter Edmunds, of a case of "Complete Prolapse of the Rectum" in which, after the failure of other operative measures the prolapsed portion was amputated with excellent results.

---

INTERNATIONAL MEDICAL MAGAZINE

for October.

Professor Bouchard of Paris, has an interesting paper on

**Albuminuria not of Renal Origin.**

Among the diseases in which albuminuria is found, but where the albuminuria in question depends on a morbid state or functional trouble of other organs than the kidneys he mentions gout, diabetes and obesity. In gouty or diabetic cases the albuminuria does not dominate the first disease but associates itself with the malady and gets better as it does, and goes away entirely if the first does. He has seen it 26 times in 100 cases of obesity—58 times in 100 cases of gout and 33 times in 100 cases of diabetes. Another variety is dyspeptic albuminuria and more particularly that form accompanied by dilatation of the stomach.

The liver may elaborate certain substances of an albuminoid nature so that albuminuria will result, again we have a cutaneous albuminuria which is of a reflex order and is provoked by excitation of the cutaneous nerves, as after rubbing a person with turpentine, cutaneous faradization or by faradization of the sciatic nerve or again by opening the peritoneum.

An intermittent albuminuria is seen in adolescents or in children during the period of growth, and when this is going on poorly, owing to dyspeptic troubles.

The treatment should not be directed to the albuminuria but to the pathogenic condition that brings it about.

Dr. Edward F. Wells, Chicago, contributes a paper and cites cases. "Note on the Curved line of Dullness in Pleuritic Effusions." As a result of his observations he says the line of demarcation is never horizontal, but is invariably curved, with its highest point in the axilla; also that when the fluid portion of a fibrino-serous exudate has been absorbed and a large quantity of fibrinous material deposited in the bottom of the sac and become organized and attached to both layers of the pleura, the line of demarcation is still a curved one, highest in the sub-maxillary region, and higher in front than behind.

**The Treatment of Posterior Urethritis by Irrigation, without the use of the Tube or Catheter,**

by G. Frank Lydston. The author believes that posterior urethritis *per se* never gives rise to a visible discharge but that when this symptom is present it is because the anterior urethra is infected. The treatment must, therefore, restore the anterior urethra to a normal condition, and to do this he irrigates the urethra through a short nozzle so the fluid may baloon the urethra thoroughly. After the anterior urethra has been thoroughly washed the patient should try to urinate while a full stream of antiseptic fluid is balooning the urethra, relaxation of the sphincter results and the fluid enters the deep urethra and bladder; this should be repeated until several quarts of fluid have been injected and ejected. For this irrigation he recommends a warm solution of boric acid with 10 grains of salicylic acid and an ounce of glycerine to the quart. This irrigation is followed by a pint of warm solution of nitrate of silver one-fourth to one grain to the ounce. This treatment is advocated only in chronic cases.

Dr. James M. Anders of Philadelphia, contributes a paper on

**The Complicating Conditions, Associated Diseases and Mortality-rate in Erysipelas.**

The author presents the following conclusions:

a. In typical cases erysipelas is a self-limited disease, the average duration in persons under forty years of age being fourteen days.

b. The course of the disease was greatly lengthened when complications were pres-

ent or chronic affections pre-existed, as well as when occurring in persons over fifty years of age.

c. Certain chronic affections, notably pulmonary tuberculosis, chronic nephritis, chronic rheumatism and organic diseases of the heart, increase the susceptibility to the complaint,—having been present in 7.8 per cent. of the total number of cases.

d. The most common complications were abscesses and acute rheumatism; the rarest meningitis and ulcerative endocarditis, pericarditis not having furnished a single instance.

e. The general average mortality was 6.57 per cent., while in the cases from private practice it was 4.16 per cent.; in persons under forty years it was only 3.5 per cent., in those over seventy years 46 per cent., and in the traumatic cases 14.5 per cent.

f. The mortality-rate was augmented as much as 25 per cent. by the presence of co-existing chronic affections.

g. The numerous complications also increased the percentage of deaths, and certain of them in an especial degree, notably labor, pneumonia, acute nephritis, delirium tremens and active delirium.

h. Age has a decisive influence upon the mortality after the forty-fifth year, this effect becoming more pronounced after the sixtieth year.

Dr. A. D. Rockwell contributes a paper on

**The Nervous Origin of Jaundice.**

The author gives at length three cases in which profound jaundice was produced from nervous causes alone.

Jaundice may be caused "through the entrance of poisons into the blood, through a deficient supply of oxygen, as in some cases of pneumonia, or where persons are habitually confined in small and ill-ventilated habitations, or where there is obstinate constipation with excessive secretion of bile, and, finally, when the individual has been subjected to extreme nervous influences, such as fright or rage, and especially the depressing influences of great grief and anxiety, the proper oxidation of the bile-acids is interfered with, bile-pigment appears in the blood, and jaundice results"—The differential diagnosis between obstructive and non-obstructive jaundice is difficult.

Between lithæmia dependent upon nervous causes and neurasthemia the following differential points are given:

The mental phenomena are different, the neurasthenian is not the victim of such irriability and unreasonable outbursts of temper.

Lithæmia is usually accompanied by obstinate constipation and by very cold hands and feet.

The tongue of lithæmia is coated more frequently and to a greater extent, and the pulse is slow rather than fast.

In neurasthenia the oxalates are frequently found in abundance, while in lithæmia the lithates are often freely deposited.

**Some Simple Methods for the Analysis of the Gastric Contents,**

by H. Lockhart Gillespie, Edinburg.

The author gives as routine practice to

1. Note the color, odor and character of the fluid obtained, with the time after food, the nature of that food, and whether any water had to be added before the stomach tube would act.
2. Filter some of the contents.
3. Determine the total acidity.
4. Test for the presence of free acid.
5. If free acid be present, find out if it is HCl.
6. Test for the organic acids.
7. Determine the presence of pepsin.
8. Investigate the nature of the proteids.
9. Test for alcohol, sugar, starch, blood or abnormal substances.

The writer considers carefully each and especially the fourth and fifth in which he considers the phloraglucin-vanillin test the most delicate and best. It is composed of phloroglucin two, vanillin one and absolute alcohol thirty parts. On drying some of the gastric contents with a drop or two of the reagent a bright red color is produced.

The remaining papers in the Journal are "An Epidemic of Diphtheria in Hightstown, New Jersey, in July, 1893, supposed to have been caused by Infected Milk" by Dr. G. H. Franklin; also "a case of Fracture of the Pelvis" by Dr. C. E. Perkins, and Clinical Lectures by Dr. W. R. Gowers on Syphilitic Hemiplegia in which he has treated the subject very thoroughly. One by Prof. Potain of Paris on The Diagnosis and Treatment of Gastric Ulcer, and a lecture on Hemiplegia; Obscure Brain Lesion; Cerebral Inanition by Dr. D. R. Brower.

# PERISCOPE.

## THERAPEUTICS.

### Eucalyptus Oil.

We recently noticed a case in which the oil obtained from the *Eucalyptus globulus* had been used successfully in the treatment of puerperal fever. The dose was three minims. The *Australasian Medical Gazett* reports a case of fatal poisoning with this drug, which occured in New Norfolk, Tasmania. Dr. Andrew Neale states that "a little over half an ounce" was taken by a boy of ten. He was in perfect health, but, the rest of the family having colds, he swallowed the oil as a preventive, recalling the

well-known epitaph, "I was well. I would be better. Here I lie." He died in 15 hours. Other cases are mentioned in which "serious symptoms" followed doses of one drachm; but this appears to be the only clearly fatal case on record. The oil appears to be a favorite domestic remedy in those parts.—*Dublin Med. Jour.*

### Tin-Poisoning.

Dr. W. A. Campbell reports six cases of gastro-intestinal disorder occuring in one family in a period of twelve days, one being fatal. The character of the alvine dejection suggested that the trouble was dysenteric. Investigation showed that the source of poisoning was the eating of tomatoes which had been preserved in cans which formerly contained peaches. These cans, having been ineffectually sealed with wax, had been reheated and resealed. A chemical examination of the contents of a can revealed a comparatively large amount of lead. He concludes:

1. Stannous salts are poisonous to the human system, being similar in their action to the other mineral poisons—lead, zinc, arsenic, antimony."
2. The salts of tin are anthelmintic as well as the powdered product.
3. Toxic doses of the salts produced symptoms similar to those from ptomaines.
4. Canned-food products may contain stannous salts in poisonous quantities.
5. The danger from this source is increased from exposure to the air; hence, all fruits should be emptied from tin cans as soon as opened. The treatment pursued in these several cases was entirely symptomatic—astringent, demulcent, anodyne, or stimulant, as the symptoms indicated. The diet was milk.—*Therapeutic Gaz.*

### Death From Salol.

At a meeting of the Biological Society of Paris, held the 27th May, M. Girode exhibited two lumps of salol weighing 1.55 grammes and 1.25 grammes, which had remained undissolved in the stomach of a woman for twelve months.

The woman died on the 20th April in the Beaujon Hospital, and when the autopsy was being made the injected condition of the great curvature of the stomach attracted attention, and when the viscus was opened the two masses of salol were found (*L'Union Medicale*, No. 64).

## MEDICINE.

### Transmission of Tuberculosis to Fœtus.

Dr. Keating says:

Unrecognized genital tuberculosis in women without pulmonary disease is not uncommon.

A tuberculous mother can transmit the disease to her offspring *in utero*.

Tuberculosis is apparently at times confined to the generative organs of women, probably with greater frequency than we now recognize.

Bacilli or their spores can be conveyed by means of seminal secretion to women when no apparent tubercular lesion is present in the male generative organs.

Women may, and often do, escape tuberculosis when transmitted in this way, and even when evidence exists of tuberculosis of of the male generative organs.

Is it not possible for the father to transmit his disease directly to the fœtus, the mother not proving a fertile soil? And, if so, is it not possible for this inheritance to become latent in the child only to manifest itself when accident or environment tends to bring it into activity? And can we not go still further and assert that the bacillus or its spores, inherited from either parent, may be carried into another generation and become manifest in glandular affections, joint troubles, or even finally in pulmonary disease?

Authorities agree that fully 50 per cent. of phthisis cases show the taint in their family record, and though the contagionist would wish us to believe that the *susceptibility* only is inherited, we feel convinced that the majority of practitioners will agree that tuberculosis, like syphilis, often gets more than susceptibility from its progenitors.—*Arch. of Pediatrix.*

### Cocaine and the Milk Secretion.

Guenel (*Gaz. Med. de Nantes*, February 12th) reports the following observation. In treating a case of cracked nipple with a 1 in 50 solution of hydrochlorate of cocaine, he found that the secretion of milk was stopped by the application. The breasts became flacid, and the nipples lost their erectility. The functional activity of the breast was restored on discontinuing the use of cocaine. —*Brit. Med. Jour.*

### Suckling and Quinine.

Oui (*Arch. de Tocologie et de Gynec.*) finds that when the mother or nurse takes quinine it has no ill effect on the child. The drug is certainly excreted with the milk, but in very small quantities. The quininized milk has absolutely no influence on the child. After a series of careful weighing and measurement, it was found that the average was the same in children suckled for a given time by nurses who had taken quinine as in children whose nurses had not taken that drug. Hence a nurse or mother may safely take quinine. Burdel's theory that quinine is noxious to the child is incorrect, aud the precautions which he recommends are therefore unnecessary.—*Ex.*

### A New Method for the Radical Cure of Varicose Veins.

Recognizing the deficiencies of these modes of treatment, we proceeded to treat the con-

dition in a manner that would remedy it at once. The two great channels that drain the superficial venous circulation of the leg are the internal or long saphena and external or short saphena veins. These and their tributaries are the vessels affected in the varicose condition. The lack of support, or any other cause, act simultaneously upon every branch of the vein. The long saphena vein commences in a minute plexus on the dorsum of the foot; it ascends in front of the inner ankle and inner side of the leg, behind the inner margin of the tibia. It drains all the anterior surface of the leg and the whole circumference of the thigh.

The external or short saphenous vein drains the posterior portion of the leg and empties into the popliteal vein between the two heads of the gastrocnemius muscle. This being the case, it occurred to me that if obliteration of the varicose veins was the essential factor in the cure, it might be possible to obliterate all the surface venous circulation by ligating the long saphenous vein at the saphenous opening and the short saphenous vein between the heads of the gastrocnemius. Blood stasis must necessarily follow and a certain amount of œdema. Elevation of the limb, and gentle compression with raw cotton and a flannel bandage soon overcomes this. Rest in bed adds the final requirement to what seemed to me *a priori* the ideal mode of obtaining a wholesale obliteration of all the varicose veins of a limb, hence the cure.

The advantages claimed for this method therefore are, first, it deals with the cases of varicose veins at wholesale; second, the operation, if *aseptic*, is harmless, easy and with the help of cocaine painless; third, it achieves that principle which we know underlies the cure of all aneurismal or varicose conditions, viz., an ultimate obliteration of the impaired blood vessel. This is reached by coagulation of blood and gradual absorption of the coagulum, while sufficient white blood corpuscles have exuded during the period of distension to subsequently build fibrous tissue which will contract upon the obliterated vein; fourth, until now we are not aware of any relapse; fifth, a cure seems apparent in from two to three weeks.—Laplace, in *Jour. Am. Med. Association.*

---

### Tracheotomy for Wasp-sting.

A curious case has been reported from Huntingdonshire. A farmer inadvertently swallowed a wasp while drinking a glass of ale. His throat began to swell immediately, and a tracheotomy had to be performed soon afterwards in order to avert suffocation. The patient was saved with difficulty.—*Med. Press and Circular.*

---

### The Early Management of Clubfoot.

Dr. De Forest Willard, in a clinical lecture of this subject offers the following conclusions:

1. The first month of life is the period of greatest growth, and to neglect treatment of club-foot during this time is to permit the bony and soft tissues to become permanently misshapen.
2. Rectification should be commenced from birth by various simple measures.
3. Correction can be accomplished by a variety of dressings.
4. Manipulation is exceedingly important for the production of a flexible foot.
5. Apparatus should be applied as soon as the foot and leg are in position for its application.
6. Rectification and manipulation should be continued up to the age when the infant is ready to walk, at which time, if the foot cannot be placed upon the sole firmly, operative measures should be instituted.—*Therap. Gazette.*

---

### Treatment of Acute Rheumatism.

℞

| | | |
|---|---|---|
| Salicylic Acid, Lanolin, Ess. Turpentine, | aa | ℥ijss. |
| Axunge, | | ℥ijss. |

Applied to the articulations, this ointment possesses many advantages. In the first place, it suppresses the pain in the space of a few hours; by it the swelling of the joint diminishes on the second day, and the fever fall completely between the third and the fifth day. Besides, *internal treatment is unnecessary*, which is of great importance, as every one knows what repugnance patients have to salicylate of soda; and, finally, it is economical.—*Med Press.*

---

### Appendicitis.

Dr. Sanborn in his paper read before the *New Hampshire Medical Society June, 1893*, concludes as follows:

(1) That in all cases the physician is concerned only in the early recognition of the disease, the subsequent treatment to be left to the surgeon.

(2) That the catarrhal or mild form of appendicitis may be considered the only medical form of the disease; and delay in operating may be encouraged to a reasonable extent.

(3) All cases of appendicitis which, at the end of thirty-six hours from the beginning of the attack, show signs of increasing disease should be operated on.

(4) That the majority of so-called recoveries, treated medically, are not recoveries in the full sense of the word, but simply a respite which enables one to settle worldly affairs, and take out a life-insurance policy, in anticipation of a fatal termination.

(5) The early surgical treatment of appendicitis enables us to avoid in every case uncertain results of a spontaneous cure, the danger of recurrent attacks, and the often fatal general peritonitis in apparently mild cases.

## SURGERY.

### The Care of Catheters.

Gouley gives the following directions for the care of catheters. Web catheters should be kept at full length to prevent cracking. In cold weather they should be warmed slightly before shaped for use. In spite of good care web catheters are liable to harden in a few years, especially if not in constant use; they then lose their shape even if they do not crack, and should be discarded. After use they should be carefully dried inside as well as out, and kept wrapped in *dry* antiseptic gauze in metal cases. Soft-rubber catheters should be kept at full length in *moist* antiseptic gauze, away from the air, as exposure causes it to become day and brittle. The life of a soft-rubber catheter is short at best, but when in daily use and anointed with fatty lubricants, they swell and become soft and useless in a few weeks. Where continued daily catheterization is necessary, it is best for the patient to have a set of ten or twelve catheters, and to use two each day, so that the same catheter may be carefully dried and sterilized, and use only every fifth or sixth day. Both web and rubber catheters are much injured by fatty substances, and even by vaselin, though to a less degree. The lubricant should be unirritating to the urethra and contain no fat or free alkali to deteriorate the varnish of web catheters or to soften the rubber catheters. The following formula has been found satisfactory: Three hundred and sixty grains of white castile soap, powdered, are added to two fluid ounces of boiling water and stirred until a homogeneous jelly is formed. Enough hot water is then added to bring the whole up to 1,200 grains, after which the mixture is strained through cotton gauze and one-half a fluid-ounce of tincture of quillaja poured into it. This mixture when cool has the consistency of honey. A little carbolic acid may be added and the lubricant kept in collapsible tubes.—*N. Y. Med. Jour.*

### Craniectomy in Idiots.

M. Bourneville, in a recent long and careful paper, has brought before the French Academy of Medicine the sum total of the results of craniectomy in deficient or idiot children. The first surgeon who attempted such an operation with a view to giving the brain more room for expansion was Dr. Fuller, of Montreal, in 1878. The child was an idiot, aged 2; the result was some improvement after a temporary paralysis. The second case was operated on by Lane in 1888, in America, and died after fourteen hours. Then, in 1890, Lannelongue took the matter up in Paris, and operated in rapid succession on twenty-five microcephalic idiots. Only one of these died from the immediate effect of the operation. Since then there have been in all fifty-six operations at the hands of Horsley, John Barlow, Keen, Bockel, Pean, and many others, which have brought about thirteen deaths. Among the forty-three children who recovered from these operations some improvement, generally very slight, is claimed in twenty-four cases. Hardly sufficient time, however, has passed since these eighty-one operations during the last three years to allow us to judge adequately of the results. The particular point to which M. Bourneville is addressing himself is the question whether in the microcephalic type of idiots the smallness of the brain is caused by the pressure due to the premature closure of the fontanelles and ossification of the sutures, for it is against such pressure that the craniectomy has been directed. There is a collection at the Bicetre of 350 skulls, most of them of idiots, and a few of them of microcephalic idiots who have been operated upon. The microcephalic idiots in general, and these cases of craniectomy in particular, do not show any signs of premature ossification. The operative openings also would not have given any considerable opportunity for the expansion of the brain, if it had had any capacity to grow further. In fact, it remains true, in M. Bourneville's opinion, not that the skull cramps the brain, but that the brain moulds the skull. (*Le Proges Med.*) —*The Practitioner.*

### Abortive Treatment of Gonorrhœa.

To abort gonorrhœa, Dr. Jamin washes out the anterior portion of the urethra several times daily for about four days with a solution of potassium permanganate of the strength of 1–4 : 1000 of water.—(*Merck's Bulletin*). The first three washes are made at intervals of about five hours; the subsequent ones, only every twelve hours. After the first injection, it is claimed, there are no more gonococci in the urethral discharge; the other washes are intended to destroy the latent germs in the urethra.

The injections of potassium permanganate, when made according to Pezzer's method, are reported to succeed very well. The liquid is injected through a red rubber catheter with thin walls and lateral perforations throughout, through which the injected fluid emerges and thus bathes the mucous surface of the urethral canal maintained dilated.—*Col. and Clin. Rec.*

### Abortive Treatment of Buboes.

It is well known that Welander, of Stockholm, has proposed to abort buboes by injecting into the beginning bubo and into the tissues about it a solution of benozate of mercury, in strength of one to one hundred. He injected a cubic centimeter of this solution, and then applied a compressing dressing. The first day the patient experienced quite lively pain; the succeeding days the injected parts became swollen and then diminished in volume, and resolution took place after a period of three weeks. Drs. Brousse and Bothezat, of Montepellier, have again taken up these experiments, but they have thought it useful, in order to well appreciate the value of this method, to pick out cases in which the pain, the inflammation and the size of the gland affected prove that there is danger

of suppuration. On the other hand, they have not experimented with patients in whom suppuration had already begun.

They have thus only been able to collect ten cases, but all picked ones, and hence not possessing a great value from the point of view of exact appreciation of the efficacy of the method. They employed the solution recommended by Welander (benzoate of mercury 1 grain, chloride of sodium 30 centigrams, distilled water 100 grains). After rendering the region aseptic (shaving, washing with soap, ether and sublimate solution), as well as the instruments and hands, they injected half a syringeful of the solution into each extremity of the gland. They then applied a sublimate compress and a compressing bandage either with cotton or with a caoutchouc band, but of the cases thus treated they had only one successful result. In all the others the evolution into suppuration continued, and they were obliged to incise. Only one case became chancroidal; the other buboes were not virulent, and hence should have been favorably influenced by the method. In all their patients the injections were followed by a state of malaise very pronounced, cephalalgia, nausea, depression and raised temperature. The authors, therefore, do not believe in the efficacy of the procedure called by the name of Welander.—*Jour. Cut. and Gentie-Uriunary Dis.*

### The Forms of Diabetes.

Dr. George Harley gives the following classification of diabetes :

1. Hepatic diabetes—including the gouty variety.

2. Cerebral diabetes—including all cases of saccharine urine arising from nerve derangements.

3. Pancreatic diabetes—the most deadly form of the disease.

4. Hereditary diabetes—a form by no means uncommon, and one, too, where both brothers and sisters may labor under the disease without either their maternal or paternal parent having been affected by diabetes, though more distant members of the family may have suffered from it.

5. Food diabetes—including all forms of saccharine urine arising from the ingestion of unwholesome substance.

In the matter of treatment, besides diet and opium or codeine, Dr. Harley recommends oroton chloral, strychnine, phosphoric acid for thirst, and an absolute prohibition of alcohol.—*Medical Record.*

### Enucleation of the Eye

Dr. Jackson, in *Philadelphia Polyclinic*, says:

To summarize, the indications for enucleation are:

1. The presence in the eye of a malignant new growth, as glioma, sarcoma, or tuburculosis. This indication is imperative no matter how much vision the eye retains.

2. The presence in the eye of a foreign body, with iridocyclitis. If the injury be recent and the inflammatory process still active, and the patient can not remain under observation, an eye with anything less than thoroughly useful vision should be sacrificed.

3. The presence of a foreign body in a blind eye.

4. Blindness with diminished tension of the eye-ball, following perforation either by traumatism or corneal ulcer, most urgent after traumatic perforation of the exposed portion of the sclera.

5. Blindness the result of irido chloroiditis without perforation of the eye-ball, if the patient cannot remain under observation.

6. Sympathetic inflammation, providing the exciting eye does not possess vision sufficiently good to be weighed against the chances of the sympathizing eye.

7. The actual presence of sympathetic irritation; not the risk of it, unless the patient is likely to be out of reach of surgical aid.

8. Persistent pain in a blind eye, sufficient to annoy its possessor or tempt him to the use of analgesic drugs.

9. Serious disfigurement of a blind eye, even if free from pain or risk of causing sympathetic disease.

### Salicylic Acid as a Tænifuge.

Dr. Ozegovski (*Muenchener med. Wochenschrift*) has spoken highly of salicylic acid in the treatment of tape worm. He administers it as follows: The patient takes no dinner nor supper, and in the evening an ounce of castor oil. The following morning a second dose of one-half ounce of castor oil is taken, and an hour after a gramme (15 grs.) of salicylic acid every hour until four doses have been ingested. If the worm is not expelled after the fourth dose of the acid, a third dose of oil of one-half ounce is prescribed.

### The Role of the Posterior Urethra in Chronic Urethritis.

Dr. Bransford Lewis, of St. Louis, in a paper read before the Association of Genito-Urinary Surgeons held in Harrogate, on the above subject, arrives at the following conclusions:

(1) The causes usually given for the prolongation of cases of clap (the presence or absence of gonococci; strictures of large calibre; the use of certain drugs in treatment, etc.) do not satisfactorily explain them, nor do they furnish reliable means for prognosticating the outcome of a case.

(2) A single widely-prevalent cause for such prolongation of gonorrhœa has as yet not proved its right to recognition as such.

(3) Posterior urethritis, by reason of its anatomlcal seclusion and inaccessibility to ordinarily prescribed treatmeut, if frequent, offers the best explanation for such prolongation or repeated recurrence.

(4) Scrutizing clinical investigation shows posterior urethritis to be present in the great majority of prolonged or severe gonorrhœa; and

(5) Direct topical treatment to the posterior urethra is therefore necessary in the great majority of cases.

(6) The causes usually given as productive of posterior urethritis are not commonly found to be real factors in the clinic.

(7) The mode of onset usually described does not coincide with that described in clinical observation.

(8) These two latter observations confirm the probability that posterior urethral infection is accomplished through the lymphatics, which explains the frequency of such infection.

(9) Posterior urethritis is not a complication, but a natural phenomen of gonorrhœa. —*Jour. of Cutan. and Genito-Urin. Dis.*

### Horse-Hair in Minor Surgery.

Dr. Thompson offers the following summary of the advantages of horse-hair in surgery:

(1) Easily obtained and inexpensive.

(2) Soft, pliable, elastic and holds a knot well.

(3) Aseptic, non-absorbent and non-irrritating.

(4) Can be used with a very small needle, and makes no shoulder at the eye.

(5) More easily removed than any other suture, without pain or injury to the tissues.

(6) Can be used for drainage.

## ARMY AND NAVY.

U. S. ARMY, FROM OCTOBER 8, 1893, TO OCTOBER 14, 1893.

Leave of absence for one month to take effect about the 20th instant is granted First Lieutenant Merritte W. Ireland. Assistant Surgeon, Fort Apache, Arizona Territory.

Leave of absence for one month, to take effect on or about October 15, 1893, is granted Captain George McCreery, Assistant Surgeon, U. S. Army, Fort Sidney, Nebraska.

First Lieutenant Allen M. Smith, Assistant Surgeon will proceed without delay to Fort Missoula, Mont., and report to the commanding officer of that post for temporary duty, to enable Capt. William D. Crosby, Assistant Surgeon, to take advantage of the leave of absence granted him.

First Lieutenant George D. DeShon, Assistant Surgeon, is relieved from further duty pertaining to the Medical section of the War Department Exhibit, World's Columpian Exposition, Chicago, Illinois, and will return to his proper station, Fort D. A. Russell, Wyoming.

Lieutenant Colonel Albert Hartsuff, Deputy Surgeon General, is relieved from duty at Fort Omaha, Nebraska, and ordered to report in person to the commanding General Department of California, for duty as Medical Director of that Department to relieve Colonel Joseph R. Smith, Assistant Surgeon General.

Colonel Smith, on being relieved by Lieutenant Colonel Hartsuff will proceed to Governor's Island, N. Y. and report in person on December 4, to the Commanding General Department of the East, for duty as Med. Dir. of that Dept.

First Lieutenant A. N. Stark, Assistant Surgeon now at Fort Clark, Texas, will proceed at once to Fort McIntosh, Texas, and report to the commanding officer, for temporary duty with troops in the field at Carrizo, Texas.

First Lieutenant Robert S. Woodson, Assistant Surgeon, U. S. Army, now temporarily at Fort McPherson, Georgia, will return to his proper station, Fort Barrancas, Florida.

Major John O'Skinner, Surgeon U. S. Army, having been found incapacitated for active service on account of disability incident to the service, is by direction of the President, retired from active Service this date, October 26, 1893, under the provisons of section 1251 Revised Statutes.

U. S. MARINE HOSPITAL SERVICE FOR THE FIVE WEEKS ENDED OCTOBER 16, 1893.

Fessenden, C. D., surgeon, granted leave of absence for thirty days, October 5, 1893.

Bailhache, P. H., surgeon, detailed as delegate to meeting American Public Health Association, October 5, 1893.

Vansant, John, surgeon, granted leave of absence for thirty days, September 23, 1893.

Hutton, H. H., surgeon, detailed as chairman Board to inspect Gulf Quarantine Station, October 17, 1893.

Hamilton, J. B., surgeon, granted leave of absence for three days, October 2, 1893.

Gassaway, J. M., surgeon, detailed as member board to inspect Gulf Quarantine Station, October 17, 1893.

Mead, F. W., surgeon, to rejoin station (Washington, D. C.) September 19, 1893.

Carter, H. R., surgeon to proceed to Way Cross, Ga., for temporary duty, October 4, 1893.

Kalloch, P. C., Passed Assistant surgeon, granted leave of absence for twenty days, October 9, 1893.

Brooks, S. D., Passed Assistant surgeon, to proceed to Chicago, Ill., for temporary duty, September 19, 1893.

Goodwin, A. T., Passed Assistant surgeon, granted leave of absence for thirty days, September 27, 1893.

Cobb, J. O , Passed Assistant surgeon, granted leave of absence for thirty days, October 11, 1893.

Guiterns, G. M., Passed Assistant surgeon, detailed as Recorder board, to inspect Gulf Quarantine Station, October 17, 1893.

Wertenbaker, C. P., Passed Assistant surgeon, granted leave of absence for seven days, September 26, 1893.

Perry, J. C., Passed Assistant surgeon, granted leave of absence for seven days, October 5, 1893.

Gardner, C. H., Assistant surgeon, to proceed to Port Townsend, Wash., for temporary duty, October 7, 1893.

Nydegger, J. A., Assistant surgeon, to proceed to Way Cross, Ga., for temporary duty, October 7, 1893.

Norman, Seaton, Assistant surgeon, granted leave of absence for four days, October 4, 1893.

Sprague, E. K., Assistant surgeon, granted leave of absence for three days, October 7, 1893.

Vol. LXIX, No. 21.

**Pharmaceutical Products of the Farbenfabriken vorm Friedr Bayer & Co.**

**Phenacetine-Bayer**

ANTIPYRETIC and ANALGESIC; Prompt, safe and effective in Fever, Influenza, Rheumatism, Neuralgia, Pneumonia, Cephalalgia and all forms of pain.

Phenacetine is given in doses of 2½ to 10 grains, 3 or 4 times daily. It does not depress the heart.

Phenacetine is supplied in ounces, also in tablets and pills, alone and with Salophen, Sulfonal, etc.

**Sulfonal-Bayer**

HYPNOTIC and SEDATIVE; Indicated in all the Insomnias including those of insanity and the Neuroses; Causes no nervous or gastric disturbances. Must be given as directed.

The dose of Sulfonal varies from 15 to 45 grains; It should be given an hour or two before bedtime.

Sulfonal is supplied in ounces, tablets and pills; also in tablets in combination with Phenacetine.

*Other Farbenfabriken Products:*

**Salophen, Trional, Aristol, Losophan, Piperazine-Bayer, Europhen.**

*New descriptive Pamphlets on these Preparations mailed by*

**W. H. Schieffelin & Co.,** New York.

IN COMBINING ANTIKAMNIA AND QUININE, ANTIKAMNIA BEING SEDATIVE IN CHARACTER, OVERCOMES ALL THE SYSTEMIC DISTURBANCES.

### THE MORBID ANATOMY OF TRAUMATIC ANCHYLOSES.*

THOMAS H. MANLEY, M. D.,† New York.

An acquaintance with the gross structural changes which attend or follow all severe injuries of the articulations, aids in opening the way to their safe and judicious treatment; beside it very materially enables us to make a forecast as to ultimate results.

In the recent past, the study of joint lesions of a pathological order, has been greatly elucidated, yet, the interpretations of bio-histological researches, are very far from being in accord.

Therefore as no final conclusions have been reached, our therapy in certain arthropathies, must for a time, at least in occasional cases be based on empirical lines.

The pathological changes in, or about a joint will be of a quality, and in proportion to the disorganization of anatomical parts in an anchylosis following an injury.

#### INTRA-ARTICULAR TYPE.

Rigidity of a joint following a traumatism, when the causation is dependent on intrinsic lesions, which are

1. Laceration, puncture, contusion or overstrain of the capsular ligaments.
2. Hemorrhage.
3. Fracture or dislocation of bone.
4. Inflammation, effusion, fibrous or osseous amalgamation of the articular surfaces.

Laceration, puncture, contusion or overstrain of a joint, is commonly, promptly followed by spasm of all the muscles above the seat of injury. Its degree is not uniform and it always is in excess, in the flexor group.

This action of the muscles serves a most salutary purpose in fixing the ends of the bones, and placing them in such a state of physiological rest as will most speedily favor functional restoration.

If the injury is not so great as to seriously involve the joint elements, but moderate reaction will follow; no febrile disturbance succeeds and by judicious treatment, in the absence of sepsis, the rigid muscles yield, when motion is again established, though a sense of weakness remains for a few days.

Certainly in those trivial phases of limitation of joint-action, as in all others, recovery will not only depend on appropriate treatment, but also on the neurotic, physical state of the patient, age, etc.

There are, however, occasionally witnessed very grave cases of joint lesion and anchylosis follow a severe contusion, torsion or sudden forced motion out of the normal range of action.

In many of this class few or no visible structural changes are apparent in the joint or overlying tissues. Yet the parts remain very sensitive to pressure or movement. I have most commonly encountered this class of cases at the tibio-tarsal and the tarso-metatarsal articulations. They are usually caused by in-

*Read at the Annual Meeting of the New York Railway Surgeons, New York Academy of Medicine, Nov. 15th, 1893.

†Visiting Surgeon to Harlem Hospital, New York.

direct violence; there is a sudden eversion or inversion, over flexion or extension of the foot, the whole weight of the body being thrown on it.

In these the predominant lesions involve the nerve trunks, the bone elements and the thecal termini of the tendons.

HEMORRHAGE (INTRA-CAPSULAR).

It is very probable that a sanguinous effusion into the hollow of synovial membranes is a common sequence of an injury borne by the joints.

The knee-joint capsule is the most capacious, superficial and distensible in the body and it is in this situation that we are the best enabled to observe the course and consequence of intra-articular hemorrhage.

Where the escape of blood has been large we will find the synovial pouch greatly distended superiorly and laterally. The limb is in an extended position and rigidly fixed by contraction of the quadriceps extensor. The patient has a sense of fullness and slight pain, but pressure moderately applied gives no discomfort.

This effusion in all the cases, which have come under my observation and have been treated by palliative measures, has rapidly vanished.

The effused blood first coagulates; it is next liquified and is finally completely absorbed and leaves no trace of it behind. But one might enquire what proof there is that the blood solidifies by clotting within the joint, or that it is completely resorbed? In answer to this, I may say, that I have three times performed an arthorotomy for the evacuation of these athromata, and, in all, the blood was coagulated though not to the same degree in each.

That it leaves no residue or deposit behind is demonstrated by the fact, that no diminution in the strength or action of the joint follows.

In the healthy individual uncomplicated synovial hemorrhage leads to no serious local or constitutional disturbance as a rule; so that the rigidity of the joint, which it entails, is only of a temporary character.

We now come to a consideration of some of those pathological changes of a grave order which threaten the mobility of the joint for all time, or seriously limit it. "When," said Gross, "motion is suspended a long time, the synovial membrane becomes dry and stiff, it eventually pours out a plastic matter, which later ossifies and totally obliterates the synovial cavity." (Gross, *Sys. Surg.*, Vol. I, p., 1091, 9th Ed,). This was essentially Callander's view of the results of the protracted fixation of a joint, though he ascribes the pernicious effects rather to organic changes in the muscles and ligaments than to those in the joint.

It is the opinion of Mansell Moullin, "that prolonged confinement of a joint in a compulsory position may cause serious stiffness after injury, and in one or two cases, in his experience, it has caused entire obliteration of the joint." (Moullin's *General Surgery*, page 419). Inflammation of a joint after an injury, when extensive and of long duration, requiring restraint of the joint, is always a condition which endangers its ultimate strength and freedom of action.

But the most interesting phase of inflammation, to the surgeon here is that of a degenerate type. Motion is Nature's stimulus to an articulation; and it is absurd to suppose, for a moment, that its protracted immobilization may be enjoined with impunity. However, a joint is but a passive organ, and, hence, we will not expect to find, perhaps, in its avascular cartilaginous surfaces, the seat of such extensive atrophic and parenchymatous changes, as will we in the structures which nourish and act on it; in the blood vessels, the muscles, bones and nerves. The circulation in the limb is feeble; the surface temperature of it is lessened, the motionless muscle undergoes interstitial degeneration, with fatty or fibrous changes in the sarcolemma. In the former the muscle has a soft, flabby feel, while in the latter, it is contractured and has a hard, resisting consistency. The bone shares in degenerative changes. The canals of Havers become narrowed and stopped with fat cells; the bone cells are diminished in number and are occupied by a granular matter. Cancellous tissue has increased, while the compact has diminished. The medulla has almost a fluid consistence and the periosteum has become very pale and brittle. The bone has become exceedingly fragile; for though it has increased in bulk, it has parted with its elasticity and strength. Persistent fixation of a joint then means the starva-

tion of those structures that give it motion; and in the end, its own functional destruction.

Inflammation of a joint, as a consequence of injury, happily is not a common condition, and when it does occur, it usually yields to appropriate measures, in so short a period, that the danger of permanent anchylosis is not imminent. It has long been an open question, whether the common arthritic anchylosis of strumous children, has or has not, its origin in traumatisms. It is true that the bacillus has been found in these cases; but that of itself proves nothing, for it is as often found in those children whose joints are entirely free. Sayre and other eminent authorities have espoused the traumatic theory; while many others of equal prominence have taken an opposite view, particularly since in our own recent times the study of the microzyme has become a craze, and germs are said to cause everything. My own impression is, that an injury is at the bottom of the vast majority of those cases. This is the class, and this only, in which the integrity of the joint is not seriously threatened by protracted fixation. This is because of the slow, very chronic course the arthritic malady pursues and because of the type of inflammation which subsists. All the vascular structures participate in the inflammatory changes in severe cases. But, to my mind, a great mistake is being committed, in a large number, by the medical attendant assuming that the case is of tubercular type, when it possesses almost none of its character.

Gross' view that immobilization leads to intra-capsular anchylosis was undoubtedly correct; but he probably was in error, when he ascribed the osseous fusion, as attributable to a low grade of inflammation of the synovial membrane. Indeed we have no proof that the articular surfaces ever solidify into one, except when there has been an ulcerative erosion and complete destruction of the cartilaginous surfaces first. And this we need scarcely look for, except in those who have long been suffering from ulcerative endarthritis.

### ANCHYLOSIS AS A CONSEQUENCE OF FRACTURE OR DISLOCATION OF BONE.

Rigidity and immobility of a limb is one of the most common symptoms of a dislocation.

With few and very rare exceptions the dislocation of most bones is readily recognized and is promptly treated.

There is a peculiar dislocation, however, at the elbow joint, apt to escape detection, unless more than ordinary care is exercised. The most constant sign of this is an anchylosis of the fore-arm, which is generally flexed from 20 to 30 degrees, only. It consists of a displacement of the head of the radius under the supinator longus, with a rupture of the articular ligament. It is a common lesion easily treated in children, and is as rare and proportionally difficult to deal with in the adult. I have seen as many as 14 to 15 of these cases in children, and have two now under my observation, in grown people: one in a man and one in a woman.

It is almost incredible that one could overlook a dislocation in any of the major articulations and regard its effects as attributable to joint disease.

At the elbow, however, there is some excuse for overlooking a luxation, when the head of the radius is displaced. If the patient be a female, with a rotund limb, a thick layer of adipose tissue conceals the lesser sigmoid notch, so that, unless special pains are taken, the displacement of bone will not be recognized. In the type of anchylosis resulting from this or other dislocations, the limb is not rigidly immobilized, but permits of more or less movement within restricted limits. It is almost needless to add that in all these cases unless recognized and rectified early, the original articular cavity, or surface, becomes obliterated and a pseudo-arthrosis is formed.

In consequence of the limitation of action and the derangement of the normal relations at the elbow, muscular inactivity, or restraint, is followed by atrophic changes and contraction in those groups, below the elbow, which serve in supination and pronation.

### ANCHYLOSIS AFTER FRACTURES WHICH INVOLVE THE ARTICULATIONS.

Anchylosis, temporary or permanent, complete or incomplete, is one of the most common concurrent or consecutive conditions of all fractures which involve the shafts. A fracture which opens into an articulation is always an unfortunate

event. It is commonly complicated by a laceration of the ligaments, with a diastasis or subluxation of the articular ends of the bones. Deformity and limitation of joint action often follow osseous union. An anchylosis which is the sequence of a fracture into a joint, presents two independent phenomena. The first succeeds in consequence of the enforced and often necessary prolonged fixation of the limb, in the course of treatment. The second arises from the morbid anatomy which follows vulnerant force, the displacement of bone, the loss of normal relations between the articular surfaces, laceration of tissue and effusion of blood. Along with the consequent acute pathological changes induced by inflammation there is a plastic effusion, which on undergoing organization and osseous consolidation seriously restricts motion ; or should this plastic deposit be copious and the joint be continuously immobilized the functions of it may be totally destroyed through an ossific union of the articular surfaces.

Osseous anchylosis following fracture is very seldom seen ; though in fractures at the elbow joint, through the humeral condyles, in Colles fracture and in a typical Pott, at the ankle in adults, more or less deformity with limitation of motion, is a common sequence, under any therapy ; though its extent is in many largely dependent on the relief measures employed.

In this type of anchylosis following fracture, it may be, in many incomplete. Bradford in discussing this subject (Bradford on Orthopædic Surgery) says : that in many joint action is limited by cicatrization of the capsular ligament and other changes in the arthritic tissues, than the bone. Watson, Price, Bryant and others maintain a similar view.

There is oftening a thickening, induration and contraction of the synovial sheath and the ligaments.

Quenu maintains that our actual knowledge of the processes of nutrition in the bones and articulations, is yet very incomplete ; for he says, that the influence of the nervous system is only too evident ; but its precise action is still problematical.

May we not invoke this theory of the influence of the nervous system on the nutrition of joints, to explain, why, in one after an intracapsular fracture, prompt union occurs with slight, if any, stiffness of the limb remaining ; every trace of inflammatory deposits having been completely resorbed ; while in others an incomplete ligamentous anchylosis follows ; and lastly, though rarely, an osseous solder has welded the articular ends into one solid, compact mass.

EXTRA-ARTHRITIC ANCHYLOSIS.

This class embraces a very large number, by all odds the most numerous.

It may be ranged under two common divisions.

1. Those cases the sequence of inflammation, or lesions of the muscles, in which definite organic changes have taken place.

2. Those in which a neurotic element plays a predominant role; or, in which stiffness of the joint follows the injury of a peripheral nerve; or, in the neurotic psychoses, as hysteria.

The best illustration of the first group we will observe in a joint below a recent fracture. At first, there is almost no motion in the joint after union of the bones has succeeded. But in most cases under appropriate treatment, in a little while muscular rigidity is overcome. There is a considerable number, however, in which anchylosis is permanent. These are seen frequently after fracture of the femur. Indeed, in many serious fractures of the shafts of bone, the surgeon is always confronted with the possible danger of anchylosis when he places the limb in an adjustment which will effect protracted immobilization. Troublesome anchylosis of the knee sometimes follows femoral fracture in adults. In these cases, there undoubtedly is at the time of injury an extensive laceration of muscular tissue by the sharp ends of the bones tearing through the muscles. It may be quite impossible to effect a perfect apposition of the separate fragments, and, hence, the rough, uneven bone ends, pushing in opposite directions, into the soft parts produce an excessive irritation; which is followed by a propagation of inflammation into the inter-muscular spaces and muscular sheaths; besides, an excessive provisional callus, which, on definite reduction in volume gathers into its grasp the adjacent tissues in such a gnarled, confused mass that they lose their distinct anatomical arrangement and cannot be thereafter isolated.

This is the most aggravated and serious type of anchylosis seen after a fracture

outside of an articulation. In anchylosis of this type, the limb varies in its attitude. When the extensor muscles, as the vasti and rectus have suffered, the position of the limb is one of extreme extension. This is the most common.

As the flexor muscles of the ham taper into tendons at about the middle of the thigh, it is only when the fracture is high up and inflammatory action spreads into the triceps that a fixed flexion is seen after a vicious union of fractured bone in the femoral region. It is a source of satisfaction to know that even in those types of muscular anchylosis but few resist remedial measures, and a fair amount of joint action is ultimately recovered.

But, in occasional cases, complete and permanent loss of all joint action follows. Sometimes, this has been designated as incomplete, or false, anchylosis, because the joint is not implicated: but, as a matter of fact, there is nothing spurious about it for the limb in grave cases is as hopelessly and irremediably crippled as though the articular surfaces were locked together by an osseous bond.

As might be expected in all severe cases of extra-articular anchylosis there is a wasting of the limb, through limitation, or total arrest of action, in certain groups of muscles. The entire limb becomes weak, the circulation is sluggish and in winter weather, the patient suffers from severe cold in the parts below the injured joint.

It may be said, of this type, that there is every gradation; that in most cases injury of the soft parts, from the sharp ends of the fractured bones, is an active factor in the causation, but not the only one. Too protracted immobilization is a passive cause; but, no less serious in its effects than the former. One cannot be entirely obviated. But by judicious management the disastrous consequences of immobilization, if they cannot be wholly overcome, can be greatly minimized.

### CASES OF EXTRA-ARTICULAR ANCHYLOSIS IN WHICH A NEUROTIC ELEMENT PLAYS AN IMPORTANT PART.

Quenu (*Chirurg. Gen. tom*, vii. p. 902). observed that by experimentally irritating the spinal nerve roots, through fine punctures the most remarkable cellular changes have been provoked in the articulations. The same author says, that he has witnessed the most distressing types of anchylosis, after injury of the peripheral nerves, especially when these have been caused by gunshot and punctured wounds. (Arthropathies, Dans Lees affections Des Nerves, Peripheriles, Vol. v. p. 393.)

This eminent writer is authority for the statement, that hysterical arthropathies generally have their starting point in trivial surface injuries. The limb, he adds, "becomes immediately painful and assumes a vicious attitude. The limb is especially hyperaesthesic over the articulation. This latter phenomenon he designates "Brodies sign," of hysterical anchylosis. The attitude, he tells us, is quite characteristic in certain cases. For instance, at the coxo-femoral it is the same as that of hip-joint disease in the third stage. At the knee, it may be either extended or flexed; in the tibio-tarsal the foot is commonly extended and adducted. Locomotion, we are told, in this class, varies from day to day: at one time, the patient walking with ease, a few steps when a few days later, the least motion gives the greatest suffering.

To my mind, it is most unfortunate that this type of articular rigidity should ever have had its present prefix.

It has no connection with the genitalia at all; is in no manner impressed by the menstrual molimen and it is not entirely confined to the female sex. In my experience, it is as common in one sex as the other, in early life. We will notice in every case, that our patient is anæmic, in adult life. My observations, in a considerable number of these cases, have convinced me that they are not, as heretofore presumed, always functional; but that they are first dependent on a tubercular cachexia, with an impressionable state of the system arising from a malnutrition of the whole cerebro-spinal system; this constituting the predisposing cause. And finally, a trauma, which under conditions of sound health would pass unnoticed, but, which here, stirs into activity dormant pathological processes.

It should be constantly borne in mind, that the primary lesions, in these cases, is outside the joint.

We may have a neuritis, and a low grade of cellulitis attended with a plastic

effusion within the muscle spaces, their sheaths and the tendons thecæ, which are undergoing fibrous changes, binds one muscle to the other, or prevents the movement of the free tendons within their envelopes. It is remarkable with what rapidity these pathological changes follow many comparatively trivial injuries, in a few days. In many we will observe a rigidity which does not yield even under an anesthetic.

Should we always recognize the true character of this class, and overcome it early, the nutrition and growth of the limb, in the child, will not seriously suffer; and recovery, in the adult, is prompt in most cases. But when we misinterpret its true character, or the case comes under observation late, consecutive changes have set in which now involve the joint structures and, we may have a formidable condition to deal with. Interstitial degenerative changes have attacked the muscles which play on the joint, a fibrosis has spread through the muscles fasciculi and destroyed their parenchymatous elements. The tubular striæ, by atrophic changes, have disappeared, or have greatly diminished in activity and number, and a rigid, stiff, unyielding contractured muscle, or group of muscles, remains. This pathological condition may involve one muscle of a group, a single, or several groups; alternately, or simultaneously.

It may be added, that in very chronic, old cases, interstitial, fatty degeneration succeeds muscular fibrosis ; and that when this sets in it spares no structure from the integument to the bone marrow. In all this class of cases, that mental impressions play an important role, is indisputable.

If the patient have sufficient will power, is docile to treatment, and is devoid of despondency; the prospect of recovery, in a brief period, is greatly enhanced.

As to the morbid anatomy in the structures, in neuro-anchylosis, so called, they are quite identical with those considered under the head of extra-articular anchylosis.

# CLINICAL LECTURES.

## COUGHS IN CHILDREN.*

W. HENRY PRICE, B. A., M. D., Philadelphia.

Gentlemen: In the routine practice of children's diseases, coughs form no inconsiderable percentage of the cases met with, and I present to you to-day three cases which will demonstrate in some measure three different classes of cough in which not only the diagnosis as to etiology is of interest but, as dependant on the diagnosis, the treatment, which is, after all, the most practical consideration —especially so far as the patient is concerned, for little they care about the pathological aspect of the question so long as they improve under treatment.

Bronchitis, either acute, subacute or chronic, forms a large proportion of cases; but not every cough is of bronchitis, and he who fails to examine carefully every case will often overlook a simply cause and utterly fail in restoring his little patient to health.

The first case is this little girl, who presents the following history:—I. R., æt. 5 years; always robust except the usual diseases of childhood—measles, whooping-cough and chicken-pox.

Two days ago she took a heavy cold which showed itself simultaneously in the head and chest—that is in hyperaemia of the nasal mucous membrane with a sensation of dryness and fullness between the eyes, and a hard, dry cough, worse at night, so that the child obtains but little sleep and that most unrefreshing. Besides this, are anorexia, constipation, malaise, coated tongue, lustreless eye and, the mother thinks, fever. Where shall we take the temperature—in the mouth, axilla or rectum? The mouth is prefer-

*Physician to the Children's Dispensary of the University Hospital and Physician to the Out-Patient Department of St. Clement's Hospital.

able for some reasons, but in a child of this age it is a trifle risky, for it is so apt to shut its teeth upon the thermometer and break it, especially in a situation like this, where one feels nervous before so many strangers. Then too the almost incessant coughing is an obstacle and would invalidate the reading even if the instrument escaped breakage. The axilla in children is inconvenient when the child is dressed and, on account of the usual leanness in this situation, the two surfaces are rarely well apposed, air enters and the registered temperature is too low. I prefer either the rectum or the groin. The latter position is cleaner and more convenient, especially in very young babies, for lying upon its back on its mother's lap, the thermometer is slipped in the fold of the groin, the mother gently flexes and adducts the thigh with her hand on the knee, and in two to six minutes, according to the sensitiveness of the thermometer, the maximum temperature is registered. Following out the method in this case we find the little girl has a temperature of 102½° F. The pulse is accelerated, but the count has little value at this moment because of the nervous excitement produced by coming before you.

Auscultation of the chest reveals the normal puerile respiration (which consists of a harsher and more prolonged expiration than is heard in adults), and on both sides, anteriorly and posteriorly, are numerous sibilant and sonorous râles.

We have here, then, a case of acute bronchitis in the first stage. You will remember that this disease is divided into two stages—the first or *dry stage*, which usually lasts about two or three days, in which there is no expectoration and physical examination shows the dry râles, either sibilant (high-pitched) or sonorous (low-pitched) or both, according to the calibre of the bronchial tube in which the sound is produced. Then the second stage or *stage of expectoration*, sets in, in which there is more or less copious discharge of a muco-purulent character; and now mucous râles replace the dry râles of the first stage. In children under six years, however, there is usually no history of expectoration as a child of this age almost invariably swallows any mucous which may be raised in a paroxysm of coughing. So far as the treatment of such a case is concerned, what is the best combination of drugs to be administered? Most therapeutists will tell you that in the first stage of acute bronchitis, where the mucous membrane is hyperæmic and dry, the only appropriate drugs are the liquifying expectorants, of which citrate of potash may be taken as the type; and above all, opium should be avoided. Our experience, however, in the children's dispensary of the University Hospital, as well as in private cases, does not bear out this testimony as to the harmfulness of opium; for while citrate of potash and its analogues will safely carry the disease into its second stage, a judicious combination containing opium, in many cases will abort the process, so that it never reaches the second stage and the little patient may be practically cured in forty-eight to seventy-two hours.

The prescription which will meet perhaps the largest percentage of cases when seen in the first stage is the following. For a child four to seven years old:

℞ Vini Antimonii..... m.iij
Syr. Scillae,
Syr. Ipecac..... āā m.v
Morph. Sulph..... gr. 1-64
Mist. Glyc. Comp.....q. s..... f. ʒi
M. Sig.—Every two hours.

If the child is not seen until the second stage is well developed or, perchance, the disease has become subacute, opium should be omitted and the ipecac and squills replaced by some more stimulating expectorants as syr. senega and ammonium choloride. The following mixture will be found a good one:

℞ Ammonii chloridi..... gr. iij
Syr. Senegae..... m.v
Syr. Prun. Virg.,
Mist. Glyc. Comp.....āā..... f. ʒ ss
M. Sig.—Every three hours.

If the secretion remains thick and tenaceous, potassium iodide in three grain-doses may be added to the above prescription for its known action in liquifying mucous secretions.

Cases often present themselves in which, through neglect or improper first treatment, the cough has run into the chronic form, with a history of having lasted perhaps one or two months. In such cases turpin hydrate or terebine, five drops on a lump of sugar, four times a day, will often effect a cure when all other drugs fail. Beyond this internal medication, a useful adjunct, either in the acute or chronic phase of bronchitis, is found in the counter-irritation afforded by rubbing

oil of amber (ol. succini) on the chest both anteriorly and posteriorly, night and morning.

By way of contrast as to etiology and treatment, let me direct your attention to a second case. This little boy, J. R., æt. seven years, came to this dispensary three weeks ago, with a history of having had a cough for three months, which had resisted all forms of treatment instituted by several physicians, and which on account of its persistency, the mother feared was beginning phthisis, and naturally was very apprehensive of his condition.

At his first visit the case seemed chronic bronchitis—numerous mucous râles were scattered throughout both chests and the case apparently in nowise differed from an ordinary one, so that we too were at first misled into the usual routine treatment applicable for cases which had reached a chronic stage. After two weeks conscientious treatment, however, finding that the lad showed no improvement, we were led to inquire more carefully into the previous history of his health. The first thing which made us suspicious was that the family resided near the banks of the Schuylkill, and following up this clue we learned that the child had had quite typical paroxysms of chills and fever.

This made us believe at once that we had here a case of malarial cough, and accordingly the treatment was changed to 3 gr. doses of quinine four times a day in syrup of yerba-santa. The improvement which followed the administration of this drug was both gratifying and instructive, and in less than one week the cough had entirely disappeared.

A third case, which serves as a text to show the importance of always making a thorough examination of your patient, is presented in this little boy, five years of age, who has a history of having had a chronic cough lasting for two years, which the mother says, came on soon after the child's convalescence from scarlet fever. Percussion and auscultation of the chest gives no explanation of the cough, but upon closely examining the fauces we find that both tonsils are greatly hypertrophied, which condition is quite sufficient to explain the perseverance of the cough. Such cases are not infrequently met with and the treatment consists in the internal administration of some alterative tonic, such as the syrup of the iodide of iron in combination with cod-liver oil, together with the local application of some astringent gargle to lessen the congestion and super-sensitiveness of the mucous membrane of the tonsils. Where the hypertrophy is more pronounced than in this case—the two tonsils sometimes meeting in the center—local applications are usually of little avail and resort to the tonsilatome must be made.

Closely allied to this, is a cough kept up by a relaxed and elongated uvula. We had one such case under treatment where, after the second day's use of a tannic acid gargle, the cough entirely disappeared.

Before leaving this subject, I cannot refrain from saying a few words about another form of cough, where, on account of its seriousness, it is highly important that a diagnosis should be made early. I refer to the cough of pneumonia. Most authorities agree that the pneumonia most frequently met with in young children and babies is the catarrhal variety and the areas involved in this process necessary to make the baby a very sick one, are often so small that diagnosis by physical examination of the chest is sometimes very hard to make. It is in this case, however, that the peculiarity of the cough gives us valuable aid in coming to a conclusion as to the presence of pneumonia.

Where the baby gives one or several short coughs, followed immediately by a suppressed cry, with an expression of pain on the face, it is very suggestive, and if this sign is accompanied by dyspnœa, in which the nasal alæ play more or less violently and the temperature is elevated, we will rarely go astray in making a diagnosis of catarrhal pneumonia, irrespective of physical signs.

---

**The Advantages of Medicine as a Career.**

Not enjoyment, and not sorrow,
Is our destined end or way,
But to act, that each to-morrow
Find us farther than to-day.

In the world's broad field of battle,
In the bivouac of life,
Be not like dumb, driven cattle;
Be a hero in the strife!

Lives of great men all remind us
We can make our lives sublime,
And, departing, leave behind us
Footprints on the sands of time.

Let us, then, be up and doing,
With a heart for any fate;
Still achieving, still pursuing,
Learn to labor and to wait.

LONGFELLOW.

# COMMUNICATIONS.

## SUPRA-PUBIC CYSTOTOMY.

O. C. STRICKLER, M. D., New Ulm, Minn.

So little is written in our surgical works of the technique, preparation and after treatment of cystotomy, that I think something in this line may be of value.

In the first place, after a case of vesical stone has been diagnosed, the question naturally presents what operation is to be selected.

Should one choose the perineal operation with its disadvantages and the long time required after operation for complete recovery, or should lithotomy and litholapaxy be considered? And what advantages has the supra-pubic operation over these different operative procedures?

We must first select an operation with low mortality, and one allowing the patient in a short time to again take up his vocation. We must admit that until late years the high operation, although seemingly an ideal one, was attended with an unusually high death rate, but aseptic surgery has removed this great objection and placed the operation on a permanent footing.

Prof. Keyes, in the *International System of Surgery*, refers to the results obtained by Billroth, "that of sloughing of the cellular tissue in the neighborhood of the wound," but this occurred in cases of children, and then before the days of asepsis. The visitor now attending Prof. Billroth's clinics finds no such results. During the time spent in Prof. Bergmann's clinic, I saw probably fifty cases without a single death.

W. W.; age forty-six; had been suffering with bladder difficulty nearly two years, and, as the pain was not constant, he neglected to call professional advice until his condition became a pitiful one. Unable to sleep; urine filled with mucopus and blood; unable to properly evacuate the bladder without assuming the recumbent position, all showing the necessity of making a thorough examination in order to discover the true state of affairs. The pain was so severe at the first and subsequent visits, that I did not at once make any exploration with a sound, but as soon as the active symptoms subsided this was done, and the characteristic "click" easily obtained.

The patient at first would not consent to any operative procedure, but after consulation with Dr. Daniels of St. Peter, Minn., and Dr. Fritsche of this city, he finally consented. The diagnosis and its evident line of treatment being so plain, we not only insisted on an operation, but that it be done as soon as the proper preparations could be made.

I first used preparatory vesical injections of a warm solution of boracic acid, four per cent., in combination with the internal use of infusion of juniper and benzoate of soda. This had a very happy effect in clearing up, to some extent, the urine, and with the use of morphia, materially reducing the cystic irritation.

The operation was performed Sept. 2, with the assistance of Drs. Fritsche and Hirsche of this city.

The pubes were shaven the day previous and strict antiseptic precautions followed throughout. In order to assist in the operation, a large curved prostatic catheter was used, which by depressing the external end caused the opposite to project against the anterior abdominal wall. Eight ounces of a warm four per cent. solution of boracic acid was then injected and retained in the bladder. In a rectal colpeurynter, which had been introduced into the bowel, twelve and one half ounces of warm water was injected by means of a common hard rubber piston syringe. This forced the bladder out of the pelvis and made the abdominal walls moderately tense. Before giving an anæsthetic, an injection should be made into the bladder to test its capacity, thereby preventing the possibility of over-distension.

The operation was then performed by making an incision about three inches in length, in the line of the linea alba, and by depressing the catheter still *in situ*, no difficulty was experienced in finding the bladder wall. The wound was then thoroughly irrigated and, after fixing the

organ with tenaculum-pointed forceps, an opening was made allowing the boracic solution to freely escape.

On insertion of my finger I found the calculus to be single, as previously diagnosed, and that the vesical walls were much thickened. The stone was then extracted by means of a calculus forceps; the organ thoroughly irrigated; the bladder wound closed with fine silk, by means of a double continuous suture, bringing the serous coats together without penetrating the bladder wall. The wound was then packed with iodoform gauze; a soft catheter introduced to allow permanent drainage and the patient brought to bed.

He was unable, however, to retain the catheter, so that I was compelled to draw the urine every three to four hours. Some urine escaped through the wound twice, but at no time was the temperature above 99°, and on the fifth day the patient had a natural evacuation, although I occasionally drew the urine until tenth day.

The patient returned to his home two weeks after the operation, September 16, and was again at his work on the twenty-third day.

The urine after the tenth day became clear and has remained so.

That such results are possible, speaks volumes for the operation; not that a conclusion can be drawn from one case, but the results where strict antiseptic precautions are followed are such that the high mortality rates for this operation (33 per cent.) quoted previous to the days of Lister, should not now be held to be the correct ratio. I might give mortality figures as quoted by Professor Bergmann, but as I have already occupied considerable space and as I have not seen any late figures collected from different operators I will desist.

The stone in the above recorded case was of the mulberry variety, weight one hundred and twenty-seven grains (127 grains).

## DIAGNOSIS AND TREATMENT OF EMPYEMA.*

O. C. BAKER, M. D., Brandon, Vt.

In my paper I shall speak of empyema only as pus in the pleural cavity and not in the general sense of the term. My purpose in discussing this subject is to ever keep fresh the diagnosis and treatment of this condition which, as a rule, means very much to the person afflicted. A wrong diagnosis, as a rule, means death to the patient, while a correct diagnosis and proper treatment often give prolongation of life and a good degree of health. Furthermore, I can truthfully say that a wrong diagnosis is often made in this not very rare disease. In proof of this statement I can recall cases which have come under my own observation, which had existed from three months to five years, with wrong diagnosis and consequently wrong treatment.

In taking up the diagnosis of empyema I shall not be able to present many new things, but hope to refresh some minds and thus help them to be ever on the alert for this pathological condition which so often takes us unawares. The diagnosis of pleurisy with an effusion of serum or pus gives nearly the same symptoms, consequently the main question in the case to determine is whether we have an effusion into the pleural cavity or not. The difficulties of diagnosis in pleurisy belong chiefly to the earliest and latest stages of the malady. In the earliest stage the pleurisy may be latent and so beyond the possibility of diagnosis; or pain may be felt and this may be due to pleurisy, pleurodynia or other causes. The pain is occasionally referred to the loin or abdomen, thus leading to suspicion of mischief elsewhere. Few errors are more common than the attribution of pleuritic pains to pleurodynia. The pain disappears as an effusion slowly accumulates and mischief and peril perhaps hardly remediable may be the consequence. The careful observer will listen anxiously to the chest day by day, or more than daily, until a friction sound is heard; further

* Read before the Vermont State Medical Society, October 13, 1893.

mistake is impossible. Fever may be present if the case is pleurodynia, and an immediate diagnosis would then be impossible unless something characteristic in the stitch and start on deep inspiration betray the real state of things. Neuralgic and inflammatory diseases of the walls of the chest are not likely to give rise to any permanent misunderstanding. A difficulty is likely to arise in distinguishing between pericardial and a localized pleuritic effusion. In rheumatic fever and in some other diseases, pericardial may occompany or ensue upon pleuritic effusion, and when the latter is on the left side and is abundant, the limit beyond the two may be beyond defining. The practical lesson is to remember the likelihood of pericardial effusion and not overlook it if it comes.

The diagnosis between exudation and pulmonary consolidation is sometimes difficult. In acute pneumonia the course of the fever, the expectoration and other symptoms help us to a decision. Limited effusions—such as an encysted empyema, not large enough to bulge the intercostal spaces, to crush up the lung, or to displace other organs, are at times quite indistinguishable from a like extent of chronic consolidation, or abscess in the lower lobe of the lung. Such collections, though usually basic, are by no means always so, but, retained by adhesions, may occupy the upper and anterior part of the middle region, or strips or irregular districts in any direction. It may be said in general terms that a permanent very dull area remaining after an acute pleurisy or pleuro-pneumonia most probably corresponds to an encysted empyema, but not always. In such cases fever may be entirely absent, and the general condition of the patient may not suggest disease; yet such a collection of pus is sure to work mischief sooner or later. Years in some cases may elapse, but the patient rarely escapes with impunity at last.

The difficulties of distinguishing bulky effusions from pulmonary consolidations are not often great. In the former the intercostal spaces may be bulged and the moiety of the chest enlarged. It but very rarely happens that consolidation reduces the lung to silence, though this may be the case. Between intra-thoracic tumors and large pleuritic effusions a difficulty is found only in those cases in which the tumor occupies precisely one-half of the chest. This is not very uncommon especially in aneurism. It must not be forgotten too that fluid effusion may accompany tumor. A curious pulsation of uncertain explanation is often seen in empyema, and must not be mistaken for an aneurism. A hemorrhage into the pleura can be distinguished from purulent effusion only by a careful survey of all the history and symptoms. The direct physical signs help us but little. Large pulmonary cavities may be taken for encysted empyema with fistulous opening into a bronchus, and here again, although a pulmonary fistula rarely gives rise to tubular breathing unless the opening be very large or communicate with a secondary cavity, yet the diagnosis by the direct signs might be impossible. The history of the case and the state of the other lung would be important factors in decision.

The distinction between chronic phthisis and pleurisy may be difficult.

In summing up the whole matter of diagnosis of empyema, we have one test which, as a rule, clears the subject up more certainly than anything else, and that is the hypodermic needle. In any case that gives flatness on percussion and gives me any suspicion that empyema might exist, I do not hesitate to introduce a rather coarse hypodermic needle and repeat it several times, if need be, until I feel sure whether pus is or is not present. In acute pneumonia, when the case is prolonged beyond the ordinary period, I am always suspicious of a pleural effusion of serum or pus. When I hear of hepatized lung after pneumonia continuing several weeks, I am disposed to conclude there is a faulty diagnosis, for I have never met such a case in practice.

In the treatment of empyema at the present day, doubtless all physicians are agreed that pus in the pleural cavity demands immediate evacuation. Just the best way to bring this about, where, when and in what way we shall get rid of the pus, often leads to a difference of opinion. I also think we are all agreed that the treatment must be surgical. I know of no practitioner who would wait for natural processes to rid the system of the accumulated pus. I think the treatment can be readily included under the heads of aspiration, free opening with or with-

out a drainage tube, and rib resection. I have repeatedly tried aspiration and have every time been disappointed in effecting a cure. I have seen patients improve a little after aspiration, and think they were better able to undergo more radical treatment. From this experience I have learned to aspirate only if I wish to place my patient in a little improved condition, so as the better to enable him to endure further operations with safety. I have treated cases with simple free incision without and with drainage tubes. The results in the two ways have been about the same. If in the treatment it is thought best to wash out the cavity, the drainage tube is well nigh indispensable. I think some surgeons advocate that in all cases rib section of two or more ribs should be done. I have never found it necessary in any of my cases, although one case was of five years duration before external drainage was made. Doubtless rib resection is necessary in a small percentage of cases. Whether we shall wash out the cavity or not, has given rise to opposite opinions among equally bright minds. Cases of foul-smelling pus might be an indication for cleansing, while a case discharging laudable pus will give good results with simply keeping the drainage free. The precise place for making drainage is at the lowest point that it can be safely made. This is a practical point that I consider of the utmost importance. A safe guide is to always introduce an aspirating needle and draw away a few drops of pus to make sure you are not opening below the diaphragm or too close to its upper surface. Some authors instruct us to make two openings near together and pass a drainage tube in at one opening and out at the other opening. Perhaps the next author warns you to beware of the above treatment as it will act as a seton. The only bad effect that has occurred in my practice in drainage tubes is the liability to cause necrosis of the ribs.

General practitioners are, as a rule, rather timid about operating for the relief of empyema. Any physician of ordinary surgical ability need not be afraid to at least made a free incision between the ribs, only being careful not to wound the intercostal artery. This is all the operation in a majority of cases will need.

# SOCIETY REPORTS.

## FIRST PAN-AMERICAN MEDICAL CONGRESS.*

### SECTION ON OTOLOGY.

C. M. Hobby, M. D., Iowa City, Iowa, President. Max Thorner, M. D., Cincinnati, O., Secretary.

The President, in his address of welcome, laid stress upon the fact that this meeting of the first Pan-American Medical Congress would afford to the otologists of America opportunity of interchange of opinions between the north and south, the more than 100 degrees that separates the confreres; and expressed the hope that hereafter we may frequently share in similar opportunities for comparison of experience. Continuing he said: "Meanwhile we have assurance of the kindly help of our fellows from the denser populations of Europe; and I congratulate you upon the presence with us of one whom we all reverence as a master; for whether we have been pupils at Vienna, or have through literature gleaned the steps by which otology has advanced since the days of Toynbee, there is not one of us but who acknowledges a debt of gratitude for the landmarks established by Professor Adam Politzer; and I think I voice the universal sentiment of felicitation that this genius is still active, and that he is here to speak for himself. I assure you that you will hereafter rejoice to have been present."

### THE PREVENTION OF DEAF-MUTISM,

by Dr. C. M. Hobby, Iowa City, Iowa.

The proportion of deaf-mutism remains nearly constant, as judged by census returns, and taking the defective classes as

* Held in Washington, D. C., September 5, 6, 7 and 8, 1893.

a whole, viz:—insane, iodiotic, blind, and deaf-mutes, constitutes 14 per cent. of those to be considered, a total of more than 50,000. In considering how large a number may come to be considered as preventable, we are met with the assumption by teachers and authors of text-books, that 50 per cent. of the mutes are congentially so. But this is not in accordance with facts, at least for the United States, as it is readily shown that not more than 14 per cent. and probably only 10 per cent. are born deaf. Again, middle ear disease plays only a small part in the production of mutism. Severe middle ear lesions of both ears is only found in about 14 per cent. of these cases, and doubtless labyrinthine disease exists in the majority of these. Even in cases attributed to scarlet fever less than one-half exhibit distinctive lesions of both middle ears.

The principal cause of deafness resulting in deaf-mutism, is to be sought in the various forms of meningitis, occuring in the early months of life, and the resulting labyrinthine disease, cerebro-spinal fever being a prominent factor in the United States.

Prevention must come then principally from associated study of clinical history and pathology, and especially pathology little understood, of inflammations of the pia mater. Great difficulties arise from the difficulty of recognizing disturbance of hearing in infants, and in the fact that the ear lesion frequently follows the acute disease without external manifestation and after a considerable interval of time. Especially should the general practioners of the country be warned of the frequency with which deafness follows apparently slight ailments of children, and they should be impressed with the fact that destruction of hearing most frequently takes place without symptoms referable to the ear.

---

OTACOUSTIC TREATMENT — ITS HISTORY AND RESULTS UPON THE DEAF AND DEAF-MUTES,

by J. A. Maloney, M. D., Washington, D. C.

Experimentation in physics, and principally acoustics, prior to 1886, resulted in the development of the instrument, since known as the otophone, which differed in construction from anything used for that purpose. It had two chief characteristics:

1. It did not enter the meatus auditorious externus.

2. It was a tube closed at one end by a flexible membrane, and thereby confined a column of air.

The instrument was demonstrated before the College of Physicians, of Philadelphia, in 1887, and subsequently tests were made upon deaf mutes at the "Pennsylvania Institution for the Deaf and Dumb," and at the "National Deaf Mute College," Washington, D. C.

It then occurred to the author that a new field of treatment in chronic deafness might be opened. A great deal then was dependent upon tentative deduction. In the use of Politzer's inflation slight benefit was conferred by equalizing the pressure upon each side of the membrana tympani. In the use of the otoscope success was rare, because it produced noise, and the ear in the higher and lower animals shrinks from the same.

Then he directed his attention to a system of aural massage, which had for its chief feature sound arbitrarily applied as a therapeutic agent in chronic deafness, and designated by him as "otacoustic treatment," which has since been known by that title. Much time was required in formulating the method of treatment during the first two years, the work being empirical because he had no rule of procedure based upon experience of others for his guidance. That partial anchylosis could be relaxed by this form of passive motion was accepted by some of the most eminent otologists of our day, and he was encouraged by them to persevere. A number of cases was then reported, showing the good results of otacoustic treatment upon deaf and deaf mutes.

Prof. Adam Politzer demonstrated a large collection of magnificent anatomical and pathological specimens. He also exhibited a number of new and improved ear instruments.

---

"PATHOLOGICAL CONDITIONS FOLLOWING PIERCING OF THE LOBULES OF THE EAR,"

by Dr. Max Thorner, Cincinnati, Ohio.

The custom of piercing the lobules of the ear for the purpose of wearing earrings is considered a relic of barbarism and superstition. Not rarely serious and

even fatal consequences have been observed after this procedure. Scattered through medical literature we find reports of trismus, erysipelas, severe inflammations, disfigurations, formation of tumors, etc., mentioned as possible sequelæ of this reprehensible custom. The following cases have come under the observation of the author:

*Erysipelas of the auricle.* Three cases. The first was a child two years old, the two others adults, in whom a severe attack of erysipelas, spreading over neck, scalp and face, developed soon after the placing of the ear-rings.

*Deformities.* Two cases of cleft lobule were seen, caused by the ear-rings cutting through the lobe. In one case the ring had been replaced close to the slit left by the first ring, and there resulted a lobule consisting of three narrow strips. An operation after the method of Knapp, gave good cosmetic results. In another case the opening made for ear-rings had become enlarged to the size of a lead pencil. The opening was closed by one suture after paring the edges.

*Eczema of Auricle*, acute as well as chronic, was observed in a number of cases. The acute form yielded readily to treatment with ointments (*e. g.* Ung. Diachylon), after the ear-ring had been removed. The chronic form is more obstinate.

*Tumors of Auricle:* Three cases: One case of fibro-chondroma of auricle in a white lady, aged 32. Began to make its appearance ten years ago. Was twice removed, but reappeared soon. About three years ago had reached the size of a small chestnut, involving the whole lobe. Was then removed by a V shaped excision, and had not returned two years after the operation.

The second case was a typical fibroma of the auricle. The patient was white, 35 years old. When 15 years old her ear-rings were caught on a pillow, and both forcibly torn out. A lump began to grow in both lobules, which were partially amputated two years later. The left tumor has never returned. The tumor in the right ear returned six times. Two years ago the tumor had reached the size of a large English walnut, involving the larger part of the auricle. The whole auricle was then amputated. The tumor has not returned.

The third case was that of a keloid of the auricle and face. The patient was an unmarried lady, white, 35 years old. When 18 years old a small, very painful tumor developed in the edge of the puncture made for ear-rings. Within the following 17 years this tumor was the cause of untold misery for the patient. She had been operated upon with the knife six times, and caustics in untold quantities, electrolysis, hypodermic medication, etc., had been tried again and again. She was hardly ever free from pain, which always increased at the time of her menstruation. There was a solid, sessile tumor, about $1\frac{3}{4}$ inches in diameter, extending from the cicatricial edge of the auricle, of which the lobule was gone, into the cheek. Removal was effected by an elliptical incision in healthy tissue, and the tumor lifted with a portion of the subcutaneous adipose tissue from its location. No signs of recurrence 14 months after the operation. On former occasions the tumor commenced to reappear within six months. The microscopic examination showed the removed tumor to be a true keloid.

The author concludes that these cases are more frequent than we usually think. "And while in most cases no serious consequences result from the folly of piercing the lobes, yet there occur from time to time cases where a life is at stake, or where the enjoyment of life is seriously interfered with. It is time that this relic of barbarism ought to be relegated where it belongs,—to the by-gone follies of superstition and fashion. And the day is, I hope, not far distant, when it will be considered an evidence of brutality to have a tender and unprotected child subjected to such an unnecessary and mutilating procedure."

Discussion by Prof. Politzer and Dr. Holmes.

---

### ON A PECULIAR AFFECTION OF THE LABYRINTHINE CAPSULE AS A FREQUENT CAUSE OF DEAFNESS.

by Prof. Adam Politzer, Vienna.

The subject of the writer's paper was a particular form of deafness, occurring usually in an older person, and due to a pathological alteration of the labyrinth capsule. During the examination of a number of temporal bones of people who

had suffered from progressive deafness, the author remarked circumscribed bony protuberances in the neighborhood of the niche of the fenestra ovalis. These protuberances were of the size of a lentil, rather flattened towards the edges, and contrasted with the surrounding parts by their yellowish color. The mucous membrane of the tympanic cavity was generally normal, occasionally somewhat thickened. The fenestra ovalis was, in some specimens, of normal appearance; in others narrowed by protuberances. The stapes usually immovable; in very few specimens, however, slightly movable.

In the second edition on 'Diseases of the Ear,' published in 1887, may be found a drawing of a case of long anchylosis of the stapes. Besides changes in the stapedio-vestibular articulation, the capsule of the labyrinth shows considerable enlargement of the lacunar medullary spaces. These changes were interpreted by the author, as well as by others who had observed similar conditions, as being due to chronic interstitial middle ear catarrh.

The study of the specimens which the author demonstrated to the Section, showed that this view is not correct, and that these cases which have usually been grouped under dry, sclerotic middle ear catarrh, are in reality due to a primary lesion in the capsule of the labyrinth.

The following are the histological changes observed in the microscopical sections made from the specimens: The parts surrounding the oval window are transformed into a uniform mass of newly formed osseous tissue. The normal articulations between the stapes and oval window have entirely disappeared. The plate of the stapes is frequently thickened, even to five or six times the normal size. The ossificatory changes begin in the bony labyrinth capsule and extend towards the oval window and the plate of the stapes, sometimes even towards the cochlea and the vestibulum.

Sometimes the ossificatory changes only produce partial ossification of the stapedio-vestibular articulations so that in the same section we find one portion of the articulation completely ossified and another still membranous. The partial anchylosis explains why the hearing power for a loud voice is still retained in some cases.

The newly formed osseous tissue stains more deeply with carmine, and this difference in color enables us to distinguish the pathological tissue from the normal even with the naked eye. The number of bone corpuscles is usually increased; the lacunar and medullary spaces are generally larger, and contain fibrillar tissue, cells, blood vessels, osteoblasts and osteoclasts.

It may be well to assume that the changes are due to a primary inflammatory process in the labyrinth capsule, producing a formation of new and young osseous tissue, which successively replaces the normal bone, and by extension towards the stapes and other contiguous parts finally causes the important functional changes due to anchylosis of the stapes.

These conditions represent one form of progressive deafness; that other pathological conditions, entirely different in character, caused by chronic middle ear catarrh, such as calcifications and ossifications of the stapedio-vestibular ligament, or adhesions between the branches of the stapes and the lower wall of the niche of the oval window may often produce similar clinical symptoms is a well established fact.

Very little could be ascertained in regard to the etiology of this form of progressive deafness, as the disease was observed in old people from whom it was impossible to obtain an accurate history. In two cases gout may be assumed as a possible cause.

That syphilis undoubtedly may cause such conditions may be assumed from the investigations made by Moos, who found hyperostotic changes on the labyrinthine wall of the tympanic cavity.

Specimens and drawings were exhibited and explained by the author, illustrating the conditions described.

In conclusion, the writer refers also to the practical bearing of his investigations, in as much as these conditions demonstrate to us why our therapeutic efforts are not always crowned with success. An operation can only afford possibilities of success provided the affection in question has not yet caused anchylosis, and that even should an operation in some cases bring immediate relief, a permanent result can hardly be expected if the anatomical changes, which were exhibited in the specimens, are only considered, in as much as the affection is progressive, and even the ex-

traction of the stapes would not prevent an obliteration of the oval window.

---

ON THE APPLICATION OF STACKE'S METHOD IN CHRONIC AURAL CATARRH,

by Dr. Felix Cohn, of New York.

The results obtained by the method usually employed in excision of the ossicles have not been very encouraging, so that the author attempted the application of Stacke's method of operation,—which he calls extra-auricular, in contradistinction to the ordinary method, the intra-auricular—in these cases. Although no cases of its application in chronic aural catarrh have been as yet reported, *a priori*, this method appeared to have considerable advantages over the usual method, chiefly in that the regeneration of drum-membrane might be prevented if the entire tympanum and the limbus be removed ; that, the external wall of the attic being removed, a larger area for the impact of sound-waves on the stapes and oval window is provided ; that the intra-auricular method does not permit of thorough asepsis ; and, finally, that the field of operation being larger, the successful removal of the ossification is, in all cases, certain. As the operation was experimental, in both cases, only one ear was operated.

Two cases are reported : Case 1, Man æt. 21, operated November 21st, 1892, on left ear; suffered from severe tinnitus and progressive deafness. In left ear conversation in low voice not at all audible ; loud whisper, one inch. Six weeks after operation tinnitus entirely disappeared in operated ear ; ordinary conversation, three feet, low voice, eight feet.

Case 2, Girl, æt. 16, suffering from sclerosis and stapes-anchylosis, operated December 15th, on left ear. On examination, hears loud voice at one foot ; immediately after operation hears ordinary conversation at $1\frac{1}{2}$ feet, loud voice 8 feet. Six weeks later, hearing is reduced to condition before operation.

The author does not claim any wide applicability of this operation, or the extra-auricular method, in the present state of our knowledge of chronic aural catarrh. Though the success of the experiment has not been brilliant, it has, however, demonstrated the perfect safety of this method, and its availability in cases in which the intra-auricular method is not practicable ; with improvement in diagnosis and careful selection of cases, the author believes that better results will be attainable by Stacke's method than by the intra-auricular method.

---

OPENING THE MASTOID CELLS IN ACUTE INFLAMMATORY MIDDLE EAR DISEASES,

by Dr. L. D. Brose, Evansville, Ind.

Although the indications as laid down in the text-books for opening the mastoid cells in acute middle ear diseases seem well defined, it has nevertheless been my experience to have met with cases where, notwithstanding the symptoms present indicated mastotomy, and because of failure to get the patient's consent, or because the operation through other causes was delayed, the patients eventually recovered solely through local treatment.

Otorrhœa accompanied by pain, œdema over mastoid and fever, resisting antiphlogistic treatment for eight days (Schwartze), is an indication for mastotomy, especially if the posterior wall of external hearing canal is swollen and bulging, and deep-seated furunculosis is excluded. In acute suppurative middle ear inflammation, without mastoid involvement or pus retention, resisting usual treatment two or three weeks, mastotomy is indicated (Dr. Heiman, of Warsaw). Also as a prophylactic measure when the ear drainage is insufficient, because of swelling of the middle ear lining membrane, or size or location of drum perforation or stenosis of auditory canal. Cerebral abscess, suppurative phlebitis with sinus thrombosis, extra-dural suppuration and meningitis, even with the presence of pyæmic or septic symptoms, indicate mastotomy. Otherwise incurable and recurrent mastoid neuralgias indicate opening the mastoid.

In operating, the author follows on the whole the directions laid down by Hartmann. The operation is terminated when pus is reached. For more extensive suppuration, and where the attic is largely the seat of the disease, the posterior wall of the inner end of the auditory canal may likewise be removed, and a drainage tube at times carried through the new formed opening and out of the external meatus. Good results can be obtained equally well with chisel or trephine, more depending

upon the operator than the instruments with which the operation is performed.

---

CHRONIC DISEASE OF THE MIDDLE EAR; ITS PROGNOSIS AND SURGICAL TREATMENT,

by Dr. Albert H. Tuttle, of Cambridge, Mass.

In a brief history of the operation for removal of the membrana tympani and ossicles it was shown that, in the beginning the operation was performed for the relief of deafness; later when the operation was applied for the relief of chronic suppuration, the earlier indication was lost sight of and only at a recent date have operators removed the membrana tympani and ossicles to obtain an improvement in hearing. In the dry form of aural catarrh the writer claimed a great improvement in hearing occurs when the foot plate of the stapes is removed, especially in those cases where the deafness is marked and the stapes firmly fixed in the oval window. The operation under these circumstances is a very difficult one owing to ossific deposits in the attachments of the ossicles and an atrophy of the cruræ. When the stapes is firmly fixed the removal of the incus alone is a useless operation. In some cases, owing to the shape of the external meatus, the removal of the stapes may be impossible. The patients recover rapidly and suffer only for a few hours from vertigo which is sometimes absent.

In the suppurating otitis media the removal of the larger ossicles was recommended, but the writer promoted the reformation of the membranatympani by leaving as much as possible of its marginal attachments, on account of the belief that continual suppuration after the removal of the ossicles and treatment of the middle ear is due to mastoid disease and requires a special operation, and the greater tendency to recurrent suppuration where the cavities of the temporal bone are not protected from atmospheric influences by the presence of a protecting membrane.

The indiscriminate removal of the ossicles in cases of vertigo and tinnitus was cautioned against, and the operation only recommended where such cases as adhesions of the membrana tympani or anchylosis of the ossicles can be predetermined. In complete occlusion of the Eustachian tube the removal of the membrana tympani and ossicles is a questionable procedure, and in ossification of the membrana tympani the piecemeal removal of the deposit is recommended.

---

THE INDICATION AND PREFERABLE METHODS FOR MASTOID OPERATIONS,

by Dr. S. S. Bishop, of Chicago, Ill.

The author believes that the majority of surgeons are too conservative both as to the time selected for surgical interference and the extent of the operation. He has seen fatal results follow, (1) refusal to allow the operation; (2) after operation too long deferred; and (3) after operations that were performed too timidly to remove all the diseased tissue; but he has never known a death to occur as the direct result of the operation itself.

The disease demanding the operation is far more dangerous than the right surgical measures for its relief. Greater freedom of action and boldness of methods will add luster to the records of our work.

Dr. Bishop has formulated the following six rules by which he has been guided in deciding when to operate. The mastoid should be opened:

1. When there is acute inflammation of the bone that resists palliative treatment.
2. When repeated swellings and abscesses occur.
3. When there is bulging of the posterior and superior wall of the meatus with middle ear suppuration.
4. When there is a fistula.
5. When there are severe pains in the same side of the head as the diseased ear, resisting all other treatment.
6. When a foul otorrhœa cannot be cured by other means.

His choice of an operation is generally Schwartze's, modified according to the exigencies of each case. Stacke's method leaves too extensive a wound surface, and it takes too long to heal. There is a tendency to resulting stenosis of the external meatus that demands the use of supporting tubes.

Light reflected from a forehead mirror is preferred; and the wound is kept partly open with iodoform gauze until it heals from the bottom. Aristol is the best cicatrizant and has soothing or anæsthetic properties.

DISCUSSION ON THE PRECEDING FOUR PAPERS.

Dr. C. R. Holmes, in opening the discussion, could not agree with Dr. Cohn that the operation by the Stacke method was more aseptic than when the operation was performed through the external canal. The results from the operation in chronic catarrh of the middle ear have been anything but satisfactory, and therefore there is little to justify us in making such an extensive operation as proposed.

He did not think that drills and trephines, as mentioned in Dr Brose's paper, should even be considered as a part of the armamentarium of the modern aural surgeon. They are instruments that had their day and defenders, but are (and justly so) relegated to the past. He was not in favor of using the drainage tube, as described by Dr. Brose, passing through the opening in the mastoid into the middle ear and out of the external canal because if the disease warranted such an extensive interference with the middle, ear, the method of operation was not radical enough; and if only for the purpose of giving vent to the mastoid cells, it is not good surgery to meddle so much with the middle ear and endanger the position of the ossicles.

He had examined cases where the stapes had been removed; Schwartze's and Lucae's experience had been very unsatisfactory. He read a letter recently received from Prof. Schwartze and another from Dr Stacke, wherein both spoke unfavorably of the operation; and Prof. Schwartze, referring to the reports by Dr. Jack, declared that the time for judgment upon those cases is entirely too short, and at present he does not believe the results will be what has been claimed.

He agreed with Dr. Bishop that aural surgeons had been to conservative in operating, and it was especially true that many did operate, but were too timid. If we have once determined that it is necessary to operate, we should use the utmost care to guard against opening into dangerous parts, but we should be bold enough to remove all the diseased tissue. He also begged to call the attention of the gentlemen to the fact that Wilde's incision should not be practiced. Schwartze has omitted it in his last work, because it is painful, and if the disease has advanced far enough to warrant the operation, the cells in nearly every case are also involved, and the patient can only be benefited by opening the bony cortex.

If the flap is formed from the lining of the external canal according to Stacke, there can be no collapse after the operation; and with proper packing, stenosis should never occur. In the experience of the speaker, the canal will admit of the largest sized speculum being used; and every part of the cavity can be freely inspected. We do not expect the cavity formed by the removal of diseased tissue to be filled with cicatrical tissue. In fact, this is the most undesirable thing that can happen. What we do want is a cavity covered with healthy epithelial cells; and this can never be accomplished unless firm and persistent packing is practised until all of the cavity is covered with epithelium.

Prof. Politzer remarked that he never opens the antrum in acute cases. The mastoid trouble is in acute cases rarely in communication with the antrum, and it is better to open simply the mastoid cells. We have thus a clean wound which heals rapidly. Of late he has tamponed the wound for one or two days with iodoform gauze, in fact has sometimes closed the wound immediately after the operation, after having scraped away all diseased bone. The patients were able to leave the hospital after one week.

In cases of chronic sclerotic middle ear catarrh he does, on the whole, not expect to get good results from the extraction of the ossicles. In some cases the operation is liable to impair the condition of the ear. In chronic purulent cases he thinks we must expect little from the extraction of the ossicles alone. Kuster's method of opening the attic and antrum has been by him employed with good results.

Dr. Felix Cohn wished to state distinctly that he is not an advocate of the excision of the ossicles in aural catarrh; but he has reported the two cases after having satisfied himself of the applicability of the method. He believes that there are only a few chronic conditions in the tympanic cavity, in which excision of the ossicles will produce permanent results; and the operations ought to be limited to the prevention of a progression of the disease, or for cases of insufferable tinnitus, so that even an otologist commanding a very large material will not find occasion to operate many cases. As

to the technique, he thought that the extra-auricular (Stacke's) method was just as advisable, if not preferable, to the intra-auricular procedure. However, wholesale excision of the ossicles should be condemned.

Dr. Bishop, closing the discussion, said that he did not often insert a drainage tube in the wound of the mastoid operation. The superficial opening is maintained by a pledget of iodoform gauze, until the wound heals from the bottom to the opening of the bone. After Stacke's operation he has been in the habit of using a hard rubber tube in the auditory canal for one day, followed by a soft rubber tube for a few days. In regard to the removal of the drumhead and ossicles for dry catarrh of the middle ear, he had become exceedingly cautious. Four cases had come to his knowledge, in all of which the results were so disastrous as to deter him from operating for this disease. In one instance the operation was followed by total deafness in the operated ear, suppuration and vertigo. In another the tinnitus aurium increased greatly after the operation. In suppuration and necrotic processes he did not hesitate to remove the ossicles.

---

THE PHONOGRAPH IN THE TREATMENT OF DEAFNESS,

by Dr. Johnson Eliot, Washington, D. C.

The Edison phonograph is capable of producing the vibrations composing sound, those falling upon the membrana tympani are considered as feeble blows (tapotement) causing passive motion of the ossicles. Could the action be confined to the middle ear the treatment would be productive of good results, but this is impossible, as any vibration is carried through the ossicular chain to the endolymph. When the ordinary voice sounds as recorded by the phonograph were used the tympanic muscles would soon become fatigued. The labyrinth is protected from sounds of large volume by the yielding of the membraneous walls, and a special valve, the membrana tympani secondaria.

In chronic catarrhal otitis media the lining membrane is in a sclerosed condition and the valve action is greatly interfered with. Where these conditions are present the vibrations are thrown back on Corti's organs which are over-stimulated. In thirteen cases reported the treatment was given about every third day for periods varying from one to seven months. In but one case did the tinnitus abate, and this for a day when it returned. None of the cases improved in condition. In one case "nervous prostration" occurred in the course of treatment. In some a slight giving away of the adhesion was noticed.

---

CLINICAL CONTRIBUTION TO THE STUDY OF AURAL SYPHILIS,

by Dr. Max Toeplitz, of New York.

Report of a case in which the labyrinth was affected primarily in the course of a freshly acquired syphilis, and in which the aural affection began simultaneously with the appearance of roseola. The special features of this case are: 1, The affection of the labyrinth occurred after the appearance of the pharyngeal mucous patches. 2, The aural lesion took place during the secondary stage, and without attacking the middle ear. 3, The diagnosis of syphilis was made from the ear. The case improved under anti-syphilitic treatment.

---

THE PRESENT CONDITION OF OTOLOGY IN EUROPE,

by Dr. Laurence Turnbull, of Philadelphia.

In the first part of this paper the author relates his observations in the otological clinics of Europe during a visit in 1892 and 1893. He compared the present position of otology with that of twenty years ago, and found everywhere a more perfect knowledge of the normal, pathological and microscopic anatomy of the ear, both in men and animals. With this precise knowledge of anatomy there followed a more rational use of therapeutics both in their local and general application. Definite operative and mechanical methods of treatment, with perfect illumination by gas or electricity, are the general rule nowadays. The old empirical use of the syringe with hot alkaline solutions, without looking into the ear, has, among general practitioners, entirely disappeared. An important union has taken place between the laryngologist, rhinologist, and the otologist, which

happy combination was well illustrated at the meeting of the British Laryngological and Rhinological Association, and at the Section of Otology and Laryngology at the meeting of the British Medical Association, at Nottingham, 1892. The author then continues to describe the methods, as practiced at present by the representative otologists of Great Britain, Germany, Austria, Belgium and France.

The second part of his paper has the separate title:

THE OPERATION OF EXCISION OF THE OSSICLES IN CHRONIC SUPPURATIVE, OR NON-SUPPURATIVE (PROGRESSIVE SCLEROSIS OR PROLIFEROUS) DISEASE OF THE MIDDLE EAR: WITH CASES.

In chronic suppurative disease of the middle ear, after all ordinary measures have failed, the excision of the membrana tympani and ossicles is resorted to for relief or cure of carious necrosed bone, or diseased tissues causing mechanical obstruction to the entrance of sound, and is now a well established rule of practice, as well as a decided advance in aural surgery.

The operation of 'otosclerectomy,' or the surgical removal of all or part of the sclerosed and anchylosed conductors of sound in non-suppurative or chronic middle ear inflammation has received the sanction of the aurists of the United States and of many in Germany, for properly selected cases. Failures may and do occur, as well in the hands of the tyro as in those of experts. In properly selected cases the author has had good success, when he found a patient with the obstruction anywhere between the thickening and adhesions of the membrana tympani, anchylosis of the malleus with the incus. It is almost always necessary to perform a preliminary operation by a removal of an oval piece of the drum with the malleus. When we find that this opening improves the hearing, or relieves the tinnitus and vertigo, the operation has to be completed by removing the incus.

In dry progressive sclerosis an incision in the membrana tympani posteriorly to the malleus, followed by traction on the incudo-stapedial joint has been advised. If this fails in removing the annoying symptoms, it will be safe to excise the membrana tympani and the ossicles. By this operation the author succeeded in stopping sclerosis. Some illustrative cases are reported. The following is the most interesting: A lady, æt. 46, was profoundly deaf from otitis media catarrh, chronic, of many years duration. There was in the right ear thickening of the membrana tympani, the handle attached to the promontory, and the whole malleus twisted on its axis. Eustachian tubes patulous. H. pressed contract. Tuning fork full C, auditory nerve normal, bone conduction good. Excessive tinnitus. The left ear was in similar condition. The operation was performed, chloroform and ether being used, Feb. 5th, 1892. The malleo-incudal joint was firmly anchylosed. The membrana tympani and part of the malleus were removed, though the operation was attended with some difficulty on account of the ensuing hemorrhage. The hearing was greatly improved after the operation, and continued so that she could hear an ordinary voice; the tinnitus had decreased. June 1893 hearing continued perfect in the ear operated upon; a new membrane had formed.

In these operations it has not always been found necessary to remove the incus and stapes. Also in cases of severe pain in the ear of an obscure nature with a dreadful feeling of pressure, much relief, of a permanent character, has been afforded the patients by opening the drum and disarticulating the malleus. Cases accompanied with atrophy or paralysis of the auditory nerve should not be operated upon. Great care must be taken not to injure the Fallopian canal with the incus hook. Children can be operated upon, and even old men have had their hearing restored for ordinary conversation, also experiencing great relief from tinnitus and vertigo. Accidents are liable to occur, but much can be done to prevent them. No death is known to the author to have followed the operation, but cases have been reported where the hearing power has been made worse.

Discussion by Drs. Thorner, Hobby, Maloney and the author.

---

DESCRIPTION AND DEMONSTRATION OF FOCUSSING EAR TRUMPET,

by Dr. Edmund D. Spear, of Boston, Mass.

As the cone-shaped tubes are best suited for collecting sound-waves for

transmission into the ear, one of this form has been chosen to illustrate my design for a Focussing Ear Trumpet. A tube of moderate length for convenience in handling has been taken. At the apex of the cone is attached a short tube of a diameter larger than that of the average sized auditory canal. Within this tube, which is made simply as a support, another tube, one end of which is curved, is fitted so as to move in and out. At the other extremity of this tube is fitted a short cone. As the capacity of the longer tube is limited by the various lengths of the columns of air within it, which act as resonators, the power of any given cone is practically fixed. In Williams' ear trumpet the capacity of a given cone is increased by cutting away a portion of one of its sides. In any instrument of this description the capacity of a given cone is increased by cutting away a portion of one of its sides. In any instrument of this description the capacity is likewise limited. It is possible, however, to vary within definite limits, though this has not been decided upon, the capacity of both forms of cone by means of my sliding tube with its funnel-shaped extremity. (Two instruments, a portable and a stationary one, were exhibited).

---

Dr. E. Dean, of Scranton, Pa., exhibited a set of

INSTRUMENTS FOR THE APPLICATION OF THE GALVANIC CURRENT TO THE ORIFICE OF THE EUSTACHIAN TUBE.

---

Dr. R. D. Barret, of St. Louis, Mo., had on exhibition

AN IMPROVED MIDDLE EAR POWDER BLOWER,

the essential feature of which is that it requires but one hand to introduce the mouth piece (a Hartmann intra-tympanic canula) and to work the bulb, the capsule containing the powder being immovably fixed between it and the canula. The instrument is moreover steadied by the thumb of the same hand introduced into a ring which is attached to the lower surface of the powder capsule.

---

ADENOIDS, A CONTRIBUTIVE FACTOR IN AURAL AFFECTIONS,

by Dr. M. D. Lederman, of New York.

The recurrence of the suppurative process in middle ear disease observed in children is so evidently due to the presence of these growths, that their thorough removal should be our first effort. If the patient is suffering from acute symptoms, we must delay such surgical interference until same have subsided. It matters not if this obstructing mass produces the inflammatory state by direct continuity or by inhibiting the action of the levator palati muscles, thus interfering with the proper æration of the Eustachian tube and middle ear, or whether the circulatory apparatus is influenced by the pressure exerted upon the pharyngeal veins. The knowledge that these growths are an exciting factor is sufficient evidence to urge their prompt removal. The usual method of treating the incessant discharge by irrigation and insufflations of boracic acid, thus allowing the possible absorption of the tympanic membrane and ossicles is, to say the least, a most faulty practice. If we would introduce our finger into the pharyngeal vault of young patients, suffering from these frequent purulent attacks, in the large majority of cases it would not be necessary to seek further for their origin. When a child suffering from ear disease, be it of the catarrhal or purulent variety, is a subject of adenoids, we may safely offer a favorable prognosis, providing the removal of the hypertrophied tissue can be thoroughly performed. Unless all the lymphatic tissue is ablated (and this can be readily ascertained by the introduction of the finger into the pharyngeal space), the desired results are not forthcoming. By ridding the patient of this overgrown tonsil, we not only benefit the aural complication, but materially influence the general system as well. The symptoms of mouth-breathing, restlessness at night, dull expression of face, nocturnal enuresis, are all relieved by abstracting the exciting lesion. We must not anticipate an immediate cessation of the offensive aural discharge, as it takes a few days and sometimes weeks for its final disappearance. However, some cases respond so quickly to the treatment that we are at times agreeably surprised. The instrument which has given me most satisfaction in their removal is the modified heart-shaped Gottstein curette, together with Löwenberg's post-nasal forceps improved by Dr. Gleitsmann.

Discussion by Dr. T. V. Fitzpatrick.

CRANIOMETRIC MEASUREMENT OF 500 SKULLS IN RELATION TO AURAL TOPOGRAPHIC ANATOMY,

by Dr. B. Alex. Randall, of Philadelphia, Pa.

The author has examined 500 skulls, with the aid of specially constructed calipers, in order to ascertain whether a certain relation of aural topography to the form of the skull could be established, especially in reference to the method of opening the mastoid. The result of his elaborate studies in this direction, elucidated by the detailed account of his measurements, is that, while not sufficiently extensive to be conclusive, they certainly show that the cranial index gives little pointing as to the anatomical relations likely to be met by the operator; and they prove that maximal or minimal dimensions may be encountered in any type of skull.

In the course of this meeting on motion of Dr. Laurence Turnbull, Professor A. Politzer was unanimously elected Honorary President of the Section on Otology of the first Pan-American Medical Congress.

**Homœopathists as Vivisectors.**

"Can this be true?" one is tempted to exclaim on reading that in America a homœopathic medicine is obtained from the common toad in the following way: "The live animal is fastened to a slab of cork by four strong pins stuck through the webs of the feet. Then the poles of an induction apparatus, in action, are slowly drawn over the back of the animal, whereupon the poison very soon issues from the dorsal glands. This is removed with a small horn knife and triturated—in the proportion of 1 part to 1,000 parts of sugar of milk." So the secretion from our old friend *bufo* is really a poison, and, wonder of wonders, also medicinal. Besides this extraordinary remedy the modern American homœopathist uses a number of equally nasty tissues and products. Surely if these curious medicaments have any scientific value, there should be no great difficulty in proving their virtues in these days of exact scientific research and experiment. What would Hahnemann say, one marvels, could he come back and see his disciples, modified by evolution, dosing their patients with the bile of the common fox? *Similia similibus curantur.* These eccentric pharmacists might possibly find some useful extractives in the body of anser domesticus, or the common farmyard goose—*Med. Press and Circular.*

---

**Decline in the Consumption of Liquor.**

Statistics are presented in Dr. Gould's report showing that since 1874, when the retail trade was accorded to the Gothenburg Brandy Company, the consumption of liquor has steadily declined in its district. In 1875 the consumption per inhabitant at bar trade places was $11\frac{8}{10}$ quarts per annum. In 1882 it was $5\frac{1}{10}$ quarts. In like manner the brandy bought at retail places fell from $15\frac{8}{10}$ quarts in 1875 to $8\frac{1}{10}$ quarts in 1892. The higher grade spirits also show a diminution. In 1875 the consumption was $2\frac{2}{5}$ quarts, in 1892, $1\frac{1}{10}$. The quarts per inhabitant was 29 in 1875; seventeen years later it reached low water mark at $14\frac{3}{10}$ quarts. During this period the prices of liquor advanced from $1\frac{1}{2}$ cents for a glass of brandy containing 47 per cent. alcohol to $2\frac{1}{4}$ cents for a glass containing 44 per cent. alcohol. These statistics do not include the amount disposed of by sub-licensees.

---

**Clinical Records**

Doctor (who has been asked to see an ill-developed infant): "What food do you give it?" Mother: "Nawthin'." Doctor: "But it must have some food to live upon. Do you mean to say that you give it nothing?" Mother: "No; it ain't 'ad nawthin'." Doctor: "What! nothing at all?" Mother: "No; nawthin'." Doctor: "Don't you give it any milk?" Mother: "Oh yes; I gives it some milk!" Doctor: "Then why do you say it has nothing?" Mother: "I didn't know what you meant." Doctor: "Do you give it anything besides milk?" Mother: "No; nawthin'." Doctor: "No bread?" Mother: "Yes; I gives it sopped bread." Doctor: anything else at all?" Mother: "No; nawthin' else." Doctor: "I suppose when you have your meals it gets something off the table?" Mother: "Oh yes; it picks a bit of meat and wegetables and such like when we gets our dinner."

PHILADELPHIA.

**TERMS**:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

**REMITTANCES** should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

**NOTICE TO CONTRIBUTORS**:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, NOVEMBER 18, 1893.

## EDITORIAL.

### LOCAL MEDICAL SOCIETIES.

The most important factor in the progress of modern medicine is the facility for the interchange of ideas and experiences afforded researchers and clinicians. The periodical meetings of state, national and international associations are symposia of workers in every department of medical science, and the records of these meetings are the most reliable bulletins of current work. Natural conditions render these conferences inaccessible to the everyday practitioner. They deal with abstract conditions, while he is compelled to struggle with the concrete and has little time to theorize in his continual conflict with disease and death. In dealing with general conditions a vast amount of practical information that would prove invaluable in every day experience, is buried out of sight in the vast accumulation of material.

'Congresses' are but meetings of 'associations;' 'associations' are but meetings of 'societies;' societies are but meetings of individuals. And though one may never attend the annual meetings of the state or national medical associations it is of vital importance, both to the individual and the profession at large, that the attendance at the meetings of the numerous local societies should be both regular and generous. By these meetings an *esprit de corps* is kept up that of itself is worth all the outlay of time and money expended in that direction. There are benefits innumerable both given and received at such gatherings.

Social intercourse and kindly feeling, for a time at least, take the place of that professional jealousy which so often mars the daily life and embitters the feelings of neighboring practitioners who under other circumstances would be the best of friends. The good feeling engendered and the thorough knowledge of each other obtained by this meeting together for mutual improvement, prevents the encouragement of suits for malpractice which so frequently spring from the avarice

of charity patients, the mendacity of rival practitioners and the greed of mercenary shysters who are hanging on to the ragged edge of the legal profession in a chronic process of slow starvation.

In union there is strength. When trouble of any kind does befall a reputable physician, if the profession is bound together as it should be where the local associations are strong, no injustice will be done the unfortunate pursued by greed and persecuted by legal chicanery. Malpractice suits are almost universally unjust combinations between a dishonest client and a dishonorable lawyer to steal something from a physician who has excited their cupidity by his seeming prosperity; and these unholy combinations of evil most frequently occur where the profession is divided and some doctor, fuller of hate than of wisdom, can be induced to lend a helping hand in the effort to destroy a brother.

This feature of mutual help and protection is of great importance to the individuals who are exposed to the various pitfalls that waylay the average doctor, yet there are many benefits conferred by professional communion that accrue as much to those who receive as to those who apply the ministrations of the healing art.

General practitioners as a rule, and especially general practitioners in the country, take and read but few journals. Even if they buy a great many new books the later and fresher ideas and recognized truths in medicine will become old before they receive them at all.

Meeting together in the pursuit of the latest and best things in their calling will sharpen the appetite for scientific knowledge, and when each contributes to the common fund his new acquisitions of fact and theory, there will not be so very much in the possession of the most advanced that does not find itself at home among the ranks and file.

There is much to be gained by the exchange of thought that takes place when cases are reported for discussion. One may reflect long and anxiously upon the difficult or startling cases that meet him in his daily rounds, but when he draws out the ideas and the experiences of his brethren, the very multiplicity of analogous cases with the resulting parallelism of thought banishes doubt and forbids hesitation in reaching conclusions. Hence the experience of one becomes a teacher for many and a fertility of resource, a readiness in applying methods or selecting remedies comes to all. Such conditions bring most satisfactory results and confidence born of success comes alike to doctor and patient.

The spirit of investigation may exist in solitude, but it does not often prolong its flight nor scour wide fields in seeking a solution of problems either old or new. When the emulation of contact and the stimulous of sympathy are added to the spur of necessity and the enticements of ambition, mysteries may become clear and the barest domain of science may be enriched by the conquests of the humblest.

It is not in the field of professional investigation and experience alone that an attendance on his local society brings improvement to the devotee of Æsculapius. The mere act of observing, recording and detailing ones experience develops the mind in several directions, while the discussion of questions as they arise teaches habits of rapid and connected thought and gives ability to think and talk in the presence of a crowd. In other words it often makes a medical nestor of one who otherwise would remain a mute inglorious Milton.

"Van Gilding is quite a leader of fashion, isn't he?"

"H–m–well, he hasn't had appendicitis!"

# TRANSLATIONS.

## THERAPEUTIC HINTS FROM FOREIGN JOURNALS.

IN CHARGE OF THE TRANSLATOR, F. H. PRITCHARD, M. D.

### SUPPOSITORIES FOR ACUTE ARTICULAR RHEUMATISM.

Dr. Lemanski (*La Semaine Medicale*, No. 58, 1893), speaks highly of the following suppositories in the treatment of acute articular rheumatism:

℞ Salicylate of Soda.....1 gm. (grs. xv).
Butter of Cacao.....Q. S.

Sufficient for one suppository. Make twelve such suppositories and introduce from five to six daily. This method of administering the salicylate is much more convenient than the rectal injections recently praised by a German writer, Erlanger.

### ECZEMA OF THE EAR AND EXTERNAL AUDITORY CANAL.

Prof. Gruber (*Archives de Ginecologia y Pediatria*, No. 25, 1893), recommends the following treatment of eczema of the ear and external auditory canal:

Apply a compress of cotton soaked in glycerine.

For external use he also employs:

℞ Glycerine.....50 gms. (℥jss).
Sulphate of Zinc.....75 cgms. (℈ii¼).

This formula is of service in humid eczema.

The following is also excellent:

℞ Cod-liver Oil.....50 gms. (℥jss).
Metallic Iodine.....5 cgms. (gr.j).

He also gives to weak and debilitated children the iodides, iron, etc., internally.

Locally the following salve may be used:

℞ Red Precipitate.....25 cgms. (grs. iv).
Simple Unguent.....10 gms. (℥ijss).

Apply to the ear upon a compress or a piece of cloth.

Diachylon ointment he also uses in the same manner as the above.

### STRYCHNINE IN NERVOUS VOMITING.

Dr. H. Smith (*La Semaine Medicale*, No. 58, 1893), employed strychnine in a patient exhausted with malaria and suffering with rebellious vomiting which had resisted all treatment and rendered taking nourishment almost impossible. He thereby obtained a notable diminution of the vomiting in the first twenty-four hours and, finally, its complete disappearance. Since then he has used it in vomiting, in various forms, from nervous exhaustion and has always obtained good results.

### DUBOISINE SULPHATE AS A SEDATIVE.

Prof. Albertoni (*Therapeutische Monatsschrift*, No. 8, 1893), has used duboisine sulphate as a sedative in hystero-epilepsy. In three cases the attacks ceased after an injection of four to five decimilligrams, and, after a further injection, disappeared entirely. Prof. Rabow, who has had extensive experience with the remedy, states that in agitated maniacs, almost without exception, one may obtain quiet and sleep with this remedy. One-half to one mgm. ($\frac{1}{128}$–$\frac{1}{64}$ gr.), suffices as a sedative and two mgms. ($\frac{1}{32}$ gr.) as a hypnotic. Two mgms. ($\frac{1}{32}$ gr.) of the drug he has found equal to two grams, (15 grs.) of chloral hydrate. Unfortunately, the patients soon become accustomed to the drug, though after discontinuing it for several days it may be again used. Sometimes he has employed it in combination with chloral, in doses of two grams of the latter and one mgm. ($\frac{1}{64}$ gr.) of the former, and with good results. He does not recommend it any more than he does hyoscine as a hypnotic, for, too large doses are necessary. It is not superior to other hypnotics. Its sleep is not refreshing, for, after awakening, the patients feel weary and exhausted. Yet, as a sedative, he gives it a prominent place where excited insane are to be quieted. Here it yields rapid and good results. Raging maniacs may be quieted with a very small dose and kept in bed. Isolation is rarely necessary. One-half to one mgm. will suffice as a rule. Only exceptionally did he have recourse to hypodermic injection.

Internally and hypodermically a watery solution, in the following formula, was employed:

℞ Duboisine Sulphate.....1 cgm. (gr. 1-5).
Distilled Water.....10 gms. (3ijss).

Administer at the first dose twelve to fifteen drops internally, and, subcutaneously, half a syringeful. The remedy, which is tasteless, was mostly taken without difficulty. Its action became manifest after half an hour. Often the patients would complain of feeling weak in their legs, of being weary and having a sensation in their head as if they had drunk too much wine. Then they would sit down, become quiet and sleepy, sometimes sleeping half an hour or longer. On waking they complained of dryness of the throat and of thirst. In the majority of cases the pupils were greatly dilated, the pulse increased, or reduced, in frequency. The respiration and temperature were not materially affected. He never employed more than two mgms. (½ gr.). As disagreeable after-effects he has now and then noticed diminished appetite, headache, vertigo and, once, vomiting. A directly favorable influence upon the psychic process he did not notice in a single case. Neither in mania, melancholia nor paranoia was the character of the disease altered. Only in intercurrent conditions of excitement did he now and then get the impression that by a rightly timed dose of duboisine was the attack suppressed.

---

### CHLORIDE OF AMMONIA IN CYSTITIS.

Dr. G. Corrie (*La Semaine Medicale*, No. 58, 1893), recommends the chloride of ammonia as superior to all other remedies in the treatment of cystitis of various origin. Under the influence of this drug, in doses of one or two grams (15 to 30 grains) he has observed, in cases of cystitis, the urine clear up and all the morbid symptoms disappear with surprising rapidity. It may be used in still greater doses without inconvenience and in none of his cases did he observe any disagreeable symptoms from its use.

---

### HEMPOTYSIS.

Dr. Blaschko (*Norsk Magazin for Laegevi denskaben*, No. 10, 1893), employs the following mixture in hemoptysis:

℞ Gallotannic Acid .....
Ergotine, āā..... 1 gm. (grs. xv.)
Destilled Water.....
Syrup āā..... 25 gms. (3vj).
A teaspoonful every hour.

Where there is great inclination to cough he employs the syrup of opium instead of the simple syrup. Where the hemorrhage is profuse he gives a teaspoonful every hour. He regards it as very reliable and superior to injections of ergotine which are prone to cause suppuration at the place of injection, or to ice-bags to the chest, which only increase the cough.

---

### HYSTERIA.

The following formula is spoken of highly in the *Raccoglitor Medico*, No. 8, 1893, in the treatment of hysteria:

℞ Monobromate of Camphor..... 3 gms. (grs. xlv).
Extract of Quassia..... 2 gms. (grs. xxx).
Syrup of Belladonna..... 6 gms. (3jss).
Sufficient for thirty pills.
One to three per diem.

This formula is also recommended in chorea.

---

### A CHEMICAL ANTIDOTE FOR CYANIDE OF POTASH.

Dr. Julius Kossa (*Wiener Medizinische Presse*, No. 41, 1863), has made investigations in the Pharmacological Institute of Buda-Pest, with regard to discovering a chemical antidote to the cyanide of potash. Hydrocyanic acid and its salts as a rule cause death so quickly that there is rarely time to administer an antidote. But there are cases of poisoning by bitter almonds, (weak solutions of the cyanides) where an antidote may be given. Atropine has been recommended, but it is rejected by the majority of writers. Peroxide of hydrogen has been suggested by Krohl, but it is so unstable and at the same time by no means indifferent. Kossa experimented with the permanganate of potash and found that they act very powerfully upon each other in the test-tube. Solutions of the cyanide lose their color due to an oxydation. Experiments on animals confirmed expectations, for animals to which the permanganate was given lived after ten times the deadly dose of the cyanide. The oil of bitter almonds and hydrocyanic acid yielded the same results, so that he can recommend it as a certain antidote to the acid and its compounds. In case of poisoning give from a

third to a half litre of a 5 per cent solution of the permanganate as soon as possible.

---

### TREATMENT OF ECLAMPSIA BY MORPHINE.

Dr. Kranz, (*Wiener Medizinische Presse*, No. 41, 1893), in an inaugural dissertation on the treatment of eclampsia of pregnancy and labor by morphine, claims to have employed this drug in seventeen cases with but two deaths. In these two cases the fatal termination was due to other complications which were previously present: rupture of the uterus, mitral insufficiency with nephritis. The inhibitory influence of morphine upon the attacks was very prompt, for, in several cases after administering a single dose of three cgms. (one-half grain), the attacks were definitely suppressed. In other cases the total quantity of morphine used was one grain and a quarter, in nine hours. In one case nearly one grain and a half was given in two hours and a half. Out of the seventeen cases the children were born dead in four, and in two of these the influence of the morphine could be excluded.

---

### TREATMENT OF BURNS BY SUBNITRATE OF BISMUTH.

Dr. Osthoff (*La Semaine Mèdicale*, No. 58, 1893), recommends treating burns by application of a thick paste of the subnitrate of bismuth and boiled water. This method of treatment he has tried in a large number of patients and he finds it more convenient than the use of the dry powder of the subnitrate, which has recently been recommended by German writers. After having removed with scissors, the loose shreds of epidermis, he covers all the burned surface with a paste of the subnitrate. In drying, this paste forms a thick crust which may be left in place until the burn heals, covering the cracks and fissures that form with new paste. Burns of the second degree, of great extent, heal under this dressing in ten to fifteen days. The portions that have become covered with scars, he dresses ewith antiseptics incorporated in paraffin, to make the application as consistent as possible. If too exuberant granulations form, he reduces them by salves of the nitrate of silver, the sulphate of zinc or the balsam of Peru.

---

### RECTAL INJECTIONS OF A SALT WATER SOLUTION IN ACUTE ANEMIA.

Dr. Warman, (*Muenchener Medical Wochenschrift*, No. 40, 1893), has employed rectal injections of a solution of salt water, six parts to one thousand, in a series of cases of grave anemia during labor, with excellent results. This method of procedure is much easier to carry out than the hypodermic, or, especially, the intra-venous, injection of these solutions, on account of the difficulty of assuring asepsis, and, in addition, the surface of the mucous membrane being quite extensive, absorption takes place more rapidly. He thinks that absorption is complete in four and a-half minutes, for there always appeared, within this time, the symptoms of elevation of temperature, the pulse improved and respiration and the general condition became better. Peculiarly enough improvement set in most rapidly when not warm water but cold, was employed in the injections—vaso-motor reflex excitement. Inject slowly with the patient upon the left side, and with but slight pressure. He employed this method in twenty-eight cases where there was profuse hemorrhage after normal labors or abortions, and with good results in twenty-seven. It is indicated in hemorrhages from other organs, except in those of typhoid fever where it might sweep off the crusts already formed upon the ulcers.

In a case of dangerous vomiting and diarrhœa from eating decayed food, his method was used with good results.

---

### CONSTIPATION IN DYSPEPTICS.

In *Le Progrès Médicale*, No. 39, the following formula is recommended in the constipation of dyspeptics:

℞ Colocynthine.....10 mgm. (gr. 1-5).
Powdered Belladonna. 5 cgms.(gr. j).
Bread Crumbs..... Q. S.

Sufficient for ten granules.
Two granules after each meal.

---

### SALICYLIC ACID AS A PALLIATIVE IN CANCER OF THE UTERUS.

Dr. F. Bernhardt, (*La Semaine Médicale*, No. 58, 1893), knowing that salicylic acid had a particular affinity for epi-

thelial tissues, tried it in inoperable cancers of the cervix uteri, by subcutaneous injection into the thickness of the growth. He employed the following formula:

℞ Salicylic Acid..... 3 gms. (grs. xv).
Alcohol (60 per cent).....50 gms.( ʒ jss).

One may inject by means of a syringe holding thirty drops, with a needle following the axis of the vagina, a few drops into seven to ten places in the tumor. The total quantity injected at one sitting should never exceed thirty drops. He has employed this method in five patients and in all these cases the results were excellent. The hemorrhages and fetid discharges disappeared, the general condition improved considerably, the cancerous tumor diminished in volume and the ulcerations upon its surface cicatrized. The pain caused by the injection varied from very slight to that of such intensity as to make the patient cry out. The first injection may be followed by increase of the pains and discharge, but this is of short duration.

---

### NAPHTHALINE AS A TAPE-WORM REMEDY.

The following, (*Le Progrès Médicale*, No. 38, 1893), preparations of naphthaline are recommended as expellers of tapeworms:

In children:

℞ Naphthaline.....30-50 cgms. (grs. v-viij).
Castor Oil..... .15 gms. (ʒ iv).
Essence of Bergamot gtts. ij.

To be taken at one time, fasting.

In adults:

℞ Naphthaline..... 1 gm. (grs. xv).

To be taken in one powder and followed immediately by 40 gms. (an ounce and a quarter) of castor oil.

---

### SALICYLIC ACID SALVE IN ACUTE RHEUMATISM.

Dr. Bourget (*Medicinische Neuigketten* No. 32, 1893) has made a long series of experiments on the absorption of salicylic acid when employed in the form of a salve in acute articular rheumatism. He simply rubs the joints with the ungent and applies over it a flannel bandage. Out of a large number he has found the following formula the best:

℞ Salicylic Acid.....
Lanoline .....
Essense of Turpentine, ana..... 10 gms. (ʒijss).
Lard ..... 80 gms. (ʒijss).

Within half an hour after application a strong reaction of the acid may be detected in the urine.

For ten years he has treated all his cases of acute articular rheumatism with this salve, without giving the drug internally and with the best of results. Pain ceases within a few hours, the swelling diminishes from the second day, the fever disappears completely between the third and fifth day and, finally, none of the disagreeable side symptoms are observed which are often associated with its internal administration.

---

## ABSTRACTS.

### THE IRRUPTION OF "CRANKS."

Asylums for the insane everywhere are crowded to overflowing, but evidently they do not contain all who should be within their walls. The irruption of "cranks" that has followed the assassination of Mayor Harrison by one of the ilk shows that the outside world is still uncomfortably peopled with the insane; for most of these cranks belong plainly to the form of insanity which the alienist terms paranoia—the most subtle, to a layman the most inscrutable, one of the commonest, and by far the most dangerous of mental maladies. Of a sudden these cranks seem to have sprung up like mushrooms everywhere. Yesterday not a paranoiac in sight; to-day you may stumble upon one anywhere. What does it mean?

It means not so much that the cranks have been given a new impetus, as that the sane portion of the community is momentarily alive to their presence. Of

course cranks, like other people, do copy after one another, and when one has achieved notoriety by a conspicuous crime, others will emulate his example. But quite independently of any such impetus, the cranks are constantly abroad in the land, perpetrating outrageous deeds hourly. They harass or threaten or amuse their fellow-beings, or as their mood changes, even shoot them, without exciting especial comment, until the victim chances to be a Mary Anderson or a Dr. Hall, or Russel Sage or Carter Harrison, and then the whole world gives expectant attention, and the hosts of cranks who have been hounding lesser lights unnoticed are suddenly thrust into view. And a general cry goes up, "Why are these lunatics allowed at large?

The question is pertinent, and fortunately the answer is easy. Dangerous paranoiacs are allowed at large because the public, except in momentary spasms of fear following upon some great tragedy, prefers that they should be at large. It is difficult to keep them in asylums, where they belong, simply because it is easy to find juries that will release them on writs of habeas corpus. Alienists may commit them to asylums; asylum superintendents may receive them there; but both are powerless before a writ of habeas corpus and a sheriff's jury. Any one may swear out the writ, and almost any jury may be depended upon to pronounce the patient sane and competent if his case be not one of actual raving mania. Then people and press will applaud, and it is heralded forth that a "sane man has been rescued from the living tomb of a mad-house." Suits for damages will perhaps follow, and the alienists concerned will be held up to public opprobrium for their iniquitous attempt upon the liberty of a fellow-being. It will seem to occur to no one that the jury, composed of laymen who confessedly know nothing about insanity, might be mistaken, and the half-dozen alienists who have made insanity a life study might still be in the right. A case of the kind occurred so recently in New York that it must be in everybody's mind. Does any one recall a newspaper comment that questioned the verdict of the jury? On the contrary, even the least sensational of journals pointed the editorial finger scornfully at the alienists and asked with crushing sarcasm what they thought of themselves now? Not so very long ago a paranoiac released by a jury from an asylum marched home and shot his sister. Did any one think to call upon the jury for its opinion of itself *now?*

Of course it may be said that Prendergast had never been released from an asylum in this way, having never been committed to one. But he belongs plainly to the class of insane persons who are most frequently so released. He ought to have been committed to an asylum long ago, and very likely he would have been had not alienists learned through experience to fight shy of cases of the kind, which are almost certain to bring them nothing but abuse. Chicago's sad tragedy is made all the sadder by the thought that it might so easily have been prevented. It is well, therefore, to look beyond the crank who committed the crime to the causes that operated to give him such dangerous liberty. It boots little to argue now *pro* and *con* as to the "responsibility" of Prendergast. It matters not what becomes of him, provided he is never again allowed to be at large. But the real responsibility, lying with the populace rather than with the individual, may well be seriously considered. For the moment the lesson is clear to every one. There will be a great shutting up of paranoiacs for a time. But if we may judge from the experiences of the past, most of them will presently be released again, and forgotten until the next series of tragedies brings them once more to view.—*Harper's Weekly.*

---

### Common Mistakes of Doctors.

1. To allow yourself to be agitated by the criticisms or praises of the patient's friends.

2. To allow yourself to make a display of your instruments.

11. To allow yourself to experiment or exhibit your skill uncalled for.

3. To allow yourself by look or action in a consultation to show that you are displeased, and that if you had been called first matters would have been different.

4. To allow yourself to indulge in intoxicating beverages.

5. To allow yourself to rely wholly upon the subjective symptoms for your diagnosis.—*Dietetic Gazette.*

# THE LIBRARY TABLE.

## BOOK REVIEWS.

*The Theory and Practice of Medicine Prepared for Students and Practitioners.* By James T. Whittaker, M. D., LL.D., Professor of the Theory and Practice of Medicine in the Medical College of Ohio; Lecturer on Clinical Medicine at the Good Samaritan Hospital; Fellow of the College of Physicians of Philadelphia; Member of the Association of American Physicians, of the American Academy of Medicine, and of the American Medical Association. With a Chromo-Lithographic Plate and three hundred Engravings. Octavo, 840 pages; more than three hundred Engravings and one Chromo-Lithographic Plate. Extra muslin, price, $5.7 ; leather, price, $6.50. New York: William Wood & Company.

When a man like Prof. James T. Whittaker essays a practice of medicine, we naturally have confidence to believe that his effort will be productive of much that is valuable to the general practitioner, and that all the latest ideas evolved from patient research during the past decade, will be incorporated.

The present volume quite fulfills our expectations, as it is a treatise not only up to date in its teachings, but rather ahead of the profession at large. The general scheme of the book is a good one—he divides the material into two parts: the first on *General Diseases*, and the second on *Diseases of Organs*. The first sixty-seven pages are devoted to the subject of *parasites*, which he divides first into *Ectozoa*, or those found upon the surface of the body, including a discussion of most of the skin diseases—and second, *Entozoa*, or worms in the intestinal canal. His elaboration of the ectozoa is so complete that even the bedbug (*cimex lectularis*) and mosquito do not escape notice.

The chapter on entozoa is very full and well illustrated, and includes a description of the rarer forms of intestinal parasites, such as the filaria medinensis or guinea worm of Asia and Africa; the distoma hepaticum, or liver fluke, and distoma hematobium of Egypt and Abyssinia.

Then follows the great effort of the volume, which is the consideration of the various infections occupying about three hundred pages. In the preface the author says "The most work has been put upon the infections, as the most frequent and dangerous, and at the same time, the most preventable of all diseases."

About one-twelfth of the volume is abstracted from his articles in "Wood's Reference Hand-book," Pepper's System of Medicine," "Hare's Therapeutics," and "Pepper's American text-book." A special feature of the book is that the author goes into the history of the different diseases, and recognizing that preventive medicine is to be the medicine of the future, the prophylaxis of disease holds a position of no inconsiderable importance.

The infectious diseases are illustrated by the specific, pathogenic microbes, and each is fully described.

The treatment of croupous pneumonia by the hypodermic injection of immunized serum, as well as by cold baths, shows the author is up to date in treatment.

He disbelieves the theory of inherited phthisis, and further is convinced that the prevention of tuberculosis depends upon the destruction of sputum and the sterilization of milk,—"all else is trivial."

A good feature of the work is that the etymology of diseases is given.

Fevers are illustrated by characteristic temperature charts.

This classification of certain diseases is somewhat unique, as for instance, under the head of infectious diseases he includes acute rheumatism, while gout is classified as a disease of the blood.

*Catarrhal* pneumonia is discussed under diseases of the lungs, but *croupons* pneunomia with the infections fevers.

In the chapter on diseases of the stomach, he objects to the term dyspepsia, and classifies all forms of gastric indigestion under the heading of gastric catarrh.

He is a thorough believer in treating chronic stomach troubles, by lavage, and considers this proceedure of special aid in differential diagnosis.

Dilatation of the stomach is discussed under the name of *gastrectasia* and the author is a strong advocate of the use of the galvanic current for gastralgia.

The chapter on diseases of the lungs is very thorough, and includes a full dissertation on resuscitation from drowning.

Under the title of *pneumonoconiosis* are discussed those diseases produced by the inhalation of dust, including anthracosis, siderosis, chalicosis, etc.

Contrary to the usual custom, skin diseases occupy the first part of the book.

In thoracic affections, some of the rarer conditions, not found in most books, are described, such as peripleuritic abscess (which he believes to be due in most cases to the invasion of actinomyces), subphrenic abscess, and bronchitis putrida. Tetany, he is inclined to believe, is a toxæmia.

We note the absence of any discussion upon the subjects of ephemeral and simple continued fevers and dengue. No mention is made of pancreatic disease and splenic affections are not fully considered. The chapter on nervous disorders is very full, except that disorders of sleep, as somnambulism, somnalence and somniloquism are omitted.

Barring these few omissions, the work is an authoritative one, and every page shows the genius of a scholar, physician and clinician, who has devoted himself to years of study, supplemented by the most valuable of all acquisitions, a broad practical experience.

The publishers, recognizing that they were dealing with a contribution from a man of note, have done their full share is producing a volume, which is at once, in its large type, good paper and substantial binding, a credit, both to themselves and to the author.

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

THE BROOKLYN MEDICAL JOURNAL for November. Dr. B. F. Kingsley reports a

**Case of Tubal Pregnancy with a Fatal Termination.**

The patient, a primipara, had missed her periods for five months. She was seen July 29, 1892, suffering with pain localized in the left ovarian region and an examination revealed a mass on that side. A diagnosis was then made of tubal pregnancy but operation was not done. She disappeared and one month after he again saw her and found her vomiting and purging with intense pain—she was pale, pulse small and rapid and had a pinched expression ; she was given a hypodermic of morphia and a consultation was requested for after dinner, but in the meantime she died. He thinks an attack of cholera-morbus precipitated the rupture and had an operation been done four to six hours earlier his patient's life would have been saved.

[Books and journals are crowded full of similar experiences, still delay is practiced. The statistics in these cases grows, nearly all can be saved by timely effort, skillful surgical interference. When the physician reaches the belief that he has to do with a case of extra-uterine pregnancy there is but one course for him to pursue—that is to operate at once. There is no time for "dinner" or the *siesta*. Delay means death—promptness of skillful surgical interference will save nearly all. In this reported case the symptoms were pronounced, the diagnosis early made, and correct as revealed by the autopsy. No evil could have come of immediate, intelligently directed surgical interference. To wait for absolute certainity of conditions is to wait for the undertaker.

Before rupture none of these cases can be diagnosed with absolute certainty, though so claimed by some surgeons whose *faculty of guessing* is phenominally developed. There are certain symptoms always associated with the accident which furnish our only guidance, they point the certain and only way—prompt and good surgery. These cases are constantly occurring and are of much greater frequency than is generally recognized, and the mortality would be startling if it were possible to obtain full and accurate statistics.

Morphia was given. In extra-uterine and all pelvic troubles only harm can come from the administration of an opiate ; it masks all symptoms, blunts the nervous centres and infuses both patient and doctor with a sense of security that misleads as to actual conditions.—ED.]

Dr. L. A. W. Allman contributes a valuable article on

**The Prevention of Blindness from Opthalmia Neonatorum.**

He urges every physician to make it a matter of personal responsibility and duty. The cost of maintenance of the blind population of the United States in 1880 was over $16,000,000. Of the inmates of blind asylums the number made blind by this disease were : In Copenhagen, 8 per cent. ; in Berlin 20 per cent. ; in Vienna 30 per cent. ; in Paris, among 208 young subjects, 45 per cent. (Noyes) ; in 1876 in Germany and Austria 33 per cent. (Horner).

In 1871 in Philadelphia out of 167 inmates of the blind asylum, 20 per cent. (Harlan).

He believes the origin of the disease is from the entrance into the eyes of the child, either during or after birth, of abnormal secretions from the birth canal. In the treatment he considers it "well nigh impossible to remove all possible source of contagion from the vagina" and advocates immediate applications to the eyes of the child. For this he uses Crede's method, viz. : One drop of a two per cent. solution of nitrate of silver dropped into the eyes after thoroughly washing them. He thinks that where this has failed it was because the solution did not reach the eye. He urges that this method be practiced in all cases.

[In our own experience and that of men in extensive dispensary practice this trouble can be prevented by careful and thorough anti-partum douching.—ED.]

Dr. George A. Evans has an article on "Mensuration in the Physical Diagnosis of Pulmonary Phthisis." The author considers mensuration of great importance in this affection and also in other affections of the lungs.

The cyrtometer now commonly used consists of two ribbons of soft metal, connected by a hinge of rubber tubing ; this is placed around the chest, then removed and the outline traced on paper. He gives interesting statistics from a number of cases in which the measurements have been made, with the vital capacity at different ages, heights, weight, etc. The temperature is also carefully considered.

**Lithemic Neurasthenia**

is carefully considered by Dr. Arthur Conklin Brush. He believes that here we have a neurasthenia due to the presence in the blood of certain mal-products formed by disordered hepatic action, producing direct nerve poisoning associated with symptoms arising from a general vaso motor paresis, and a disturbance of the mental condition due to direct toxic action on the cerebral cells.

The exciting causes he divides into two sets. First, those which act by producing general nervous exhaustion. Second, those which act directly upon the liver.

The physical effect produced by this disturbance of the hepatic function again divides itself into two groups. First, in one the secretion of bile is interferred with and the patient becomes anæmic, emaciated and constipated. In the other the biliary secre-

tion is not disturbed and these patients are often florid and robust, but otherwise the symptoms are the same in both sets. Among the symptoms is a feeling of intense nervousness and a feeling of impending evil, often slight melancholia. Disturbances of sensation, as numbness and neuralgic pains, are common; also fibrillary muscular twitching or tonic painful contractions of muscles. Alarming attacking of vertigo and dyspnœa are common. The pulse in the first set is usually rapid and feeble and the skin pale and cold. In the second set it is slow and strong. Tinnitus aurium, often confined to one ear, is present. Slight dyspeptic symptoms are nearly always present. The tongue is always covered by a more or less thick white or yellowish coat, there is pain, nausea and vomiting, constipation is common and the stools may be deficient in coloring matter. The urine may contain an excess of urates, oxalates and phosphates and a trace of albumen.

In treatment remove the cause if possible. Begin the treatment with a dose of calomel and soda bi-carb. For the constipation salines, but the author prefers a mixture of rhubarb, ipecac and soda; or the pill of aloes, belladonna and strychnia. To increase the functions of the liver give such drugs as are known to increase one of them, the secretion of bile; preferably a combination of ammonium chloride and ipecac. Sugar is to be prohibited and the diet to consist chiefly of vegetables, especially the green ones—with these the patient may have fruit, tea, coffee, cocoa, corn, rice bread, butter, oysters, fish, white meats and poultry.

The use of tobacco should be prohibited and plenty of exercise taken. Anæmia calls for iron and arsenic. Insomnia and nervousness for the bromides.

Dr. Frank Terry Brooks concludes his article on

**Hypertrophic Hepatic Cirrhosis.**

The paper is an interesting clinical report of a case occurring at the Long Island College Hospital.

He considers the duration of these cases to be usually between one and six years but in one whose vital powers are lowered as in his case which has lasted four and one half years, a severe attack of malarial toxæmia, throwing its force upon the already overburdened liver, a sudden cold, determining itself in this viscus, any respiratory, renal or cardiac disease which would secondarily involve the liver or another sharp acute disturbance referable to the gastro-intestinal tract would hasten the fatal issue.

Among the ætiological factors, alcohol is the most pathogenetic, while constitutional diseases of a wasting and debilitating character, such as specific troubles, chronic Brights, tubercular changes, malarial toxæmia, cardiac lesions and rheumatism, gout or the exanthemata may lead to this condition.

Pathologically considered, a cirrhosed liver is a chronic inflammatory affection of the capsule of Glisson. Macroscopically, the capsule is thickened and opaque, the liver is enlarged and firm in consistence, the cut surface is dry, anæmic and nodular.

Microscopically we find in the hypertrophic variety an increase of interlobular connective tissue and a number of nodules separated by fibrous bands are usually rich in lymphoid and spindle cells, and blood vessels. Fatty infiltration and amyloid degeneration may coexist. The contracted variety differs from it only in the amount and degree of sclerosed tissue.

Therapeutics. In the early stages remove the causes. In his case milk was the chief diet. Locally Ung. Potass. iodid. ʒi-ʒij ad ʒi was applied with massage over the hepatic region; internally the combination giving the best result was

℞ Sodii Bromidi..... gr. v.
Ac. Hydrocyanici Dil..... m ISS
Glycerol pepsinæ..... m I.
Aq. menth. pip. ad..... ʒij
M.

Many remedies have been used for this trouble as rhubarb, sodium carbonate, sol. iodi co., bi-chloride of mercury, salines, nitrate silver, etc.

---

THE ARCHIVES OF PEDIATRICS

for November. Dr. F. Forcheimer has an interesting article on,

**The Treatment of Certain Forms of Anæmia in Children.**

He presents the following conclusions:

1. In the anæmias of children the hæmoglobin suffers greater reduction than the red corpuscles.

2. If the hæmoglobin can be increased this will produce an increase in the number of red corpuscles.

3. The hæmoglobin having its principal origin in the intestine, can be increased by the internal administration of various remedies having for their action:

a. An antiseptic effect, preventing in this manner the destruction of the precursors of the hæmoglobin.

b. A direct supply of the hæmoglobin (from blood or blood products).

c. To a certain extent, by the internal administration of iron compounds.

Dr. Lewellyn F. Barker reports a case of "Diffuse Scleroderma in a Child of two and a-half months, associated with Pleuro-Pneumonia and General Streptococus-Infection."

He goes carefully into the history of this rare disease and gives the autopsy in full.

**Aetiology of Incontinence of Urine in Children.**

by Dr. B. K. Rachford. He believes there are three important ætiological factors of incontinence of urine in children.

1. Excitability of the nerve centres produced by heredity and age.

2. Anæmia or mal-nutrition increasing the excitability of the nerve centres.

3. Reflex irritation.

These factors are interdependent and act together in producing this condition.

The remaining papers are "The Treatment of Rachitis," by Dr. J. H. Fruitnight, and "A Case of False Meningocele, by Dr. Irving M. Snow.

---

THE CHICAGO MEDICAL RECORDER

for October. Dr. Richard Dewey contributes a paper on

**General Paralysis,**

reporting three cases occurring in husband and wife with syphilitic infection in each case, certain or very probable. The author concludes that if there is any cure for general paralysis it can only be in its very early stages, and at a time long before the special advice is likely to be sought, and still longer before the unfortunate sufferer is sent to the asylum. While general paralysis has been almost universally regarded as wholly incurable, yet an increasing number of cases is coming to light in which it would appear that a recovery had taken place. They must, however, be cases in which the arrest was secured in the incipient stages through early recognition and prompt treatment. The family physician, therefore, stands in the best position to recognize this increasingly frequent and justly dreaded malady and to secure the assistance which may, perhaps, avert years of suffering and the fatal sequel. Patients known to be predisposed may be advised as to their danger, and one in the prodromal stages may possibly be relieved, who at a later stage will be quite beyond help. The author fears that syphilis, communicated from husband to wife, causes a larger proportion than is generally suspected of those cases in which general paralysis appears in the female sex.

Dr. J. M. G. Carter discusses the "Relation of the Climate of the Lake Region to Catarrhal Diseases of the Respiratory Organs." As the result of his investigations he concludes that, barring the presence of pathogenic organisms, the most efficient causes of catarrhal diseases of the respiratory tract are extreme variations in temperature, high winds, moist atmosphere, large per cent. of cloudiness, and marked variations in ozone.

Dr. J. L. Hillmantell reports

**A Case of Distoma Hematobium**

occurring in an Egyptian boy of twelve years of age, employed as a donkey driver at The World's Fair. The boy complained of no pain or inconvenience. Simply the fact of his noticing blood in his urine caused him to consult a physician. He has noticed blood in his urine for the past six years, the quantity varying at different times. General health good. Temperature and pulse, which were taken daily for some time, showed no deviation from the normal. Urinalysis showed sp. gr. 1020, reaction acid, color reddish brown, albumen present about one-third by volume, and considerable sediment with clots of blood. The microscopical examination revealed red blood corpuscles, leucocytes, blood in clots, bladder epithelium in masses, bacteria—probably from external sources—and the ova of the distoma hematobium. Repeated examination of the boy's blood taken from the finger showed no special causes for the hematuria and excluded malaria, which might have come into consideration. The patient was suffering from anæmia due to the long continued drain on his blood-forming organs and the treatment was directed in the direction of aiding repair. The disease is met with only in tropical zones and it is said that over one-half the population of Egypt is affected. The paper is illustrated by woodcuts showing the ova and a fully developed parasite.

The remaining paper in this month's issue is the "Introductory Lecture" delivered by Dr. N. S. Davis before The Northwestern University Medical School.

---

LANPHEAR'S KANSAS CITY MEDICAL INDEX

for October. Dr. C. E. Ruth contributes a paper on the

**Operative Treatment of Cerebro-spinal Meningitis and Traumatic Intra-cranial Lesions without Fracture.**

The author believes that cases of cerebral or cerebro-spinal meningitis, idiopathic or traumatic, should be treated on the same principles as obtain in other parts of the body for like conditions, viz.: Evacuation of the products of inflammation, drainage, and if need be irrigation. All head injuries, without fracture, in which immediately or remotely there develops dangerous cerebral compression, call loudly for the use of the trephine. He is convinced from the pathology of cerebro-spinal meningitis that the disease is essentially a surgical disease, and that the earlier surgical aid is secured the greater will be the chances for complete and permanent recovery. He thinks that the indications are as clear in this disease for operative interference to give vent to the products of inflammation as they are in cases of suppurative otitis media with cerebral complications. The best point to drain the sub-arachnoid space is a matter worthy of careful consideration. He believes that these cases can best be relieved by an operation as near as practicable to the greatest accumulation of fluid in the base of the brain, viz.: at the right or left of the median line, below the superior curved line of the occipital bone or immediately above the superior border of the posterior third of the zygoma. After opening the dura and arachnoid in the zygomatic region, if drainage be not free, a director or drainage tube should be carefully passed towards the median line sufficiently far to accomplish the purpose and the tube may be left in or not at the discretion of the surgeon. In the occipital region care should be exercised to avoid injury of the medulla.

The author also thinks that in neglected cases where the exudation has become plastic or purulent, single or even multiple trephine openings will not be sufficient but that irrigation will be needed. After the opening is made in the occipital region on either side if it is thought desirable to irrigate we may open at or in front of the fissure of Sylvius on either or both sides. We should

make the opening in the dura only large enough to admit the irrigator nozzle, to prevent the fluid from passing out around the tube, and introduce the fluid slowly. If there are no extensive adhesions the fluid will readily pass to the posterior opening. It will be necessary to open the visceral layer of the arachnoid in some of the late cases and this should be done over the fissure of Sylvius, as the greatest amount of plastic and purulent exudation takes place along the great vessels. The fluids that commend themselves to our consideration for irrigation purposes are sterilized water containing boracic acid or hydrogen peroxide. In experimental work on the cadaver the author found that the fluid passed readily from the anterior to the posterior opening. Should the meningeal inflammation involve both cerebral and spinal meninges then it would be better to make the lower opening in the lower cervical region.

Dr. Thad. A. Reamy reports

**A Case of Abdominal Tumor with Obscure Diagnosis.**

The patient was twenty-four years of age, single, and presented all the signs of pregnancy except the fœtal heart sounds. The reporter was at first inclined to regard the case as one of pregnancy in spite of the patient's denial. At the section, some months later, the tumor was found to be a cyst in the broad ligament which had grown close to the uterus so as to convey the impression to the examining finger of an enlarged uterus. The nervous irritation caused by the presence of the cyst was sufficient to produce morning nausea and a flow of milk from the breasts.

Dr. J. H. Thompson presents

**A Contribution to the Treatment of Acute Granular Conjunctivitis.**

The author calls attention to the prevalence of the disease during the haying season as the result of the irritation caused by the flying particles of hay and dust. He advises the thorough bathing of the eye with a solution of boric acid and calcined magnesia so soon as the photophobia is removed by the use of a cocaine solution. After the eye has been thoroughly washed, a drop of a one-half per cent. solution of atropine should be instilled to relieve the keratitis which is nearly always present. As the second part of the treatment he advocates the use of a solution of bichloride of mercury and common salt.

Dr. J. W. Wilhoit contributes a short paper on "Intestinal Obstruction." The author believes that hydrogen gas is a remedy which will work well in such cases. Sulphate of magnesia he believes to be the best medical agent at hand for the relief of either acute or chronic intestinal obstruction.

The remaining papers in this month's issue are "Empyema of the Maxillary Sinus and its Relation to Diseases of the Antrum of Highmore," by Dr. Moreau R. Brown; and "The Structures Existing in the Broad Ligament," by Dr. F. Byron Robinson.

## THERAPEUTICS.

### On the Physiological and Therapeutic Influence of Testicular Liquid on the Animal Organism.

In May, 1892, MM. Brown-Sequard and D'Arsonval arranged to supply organic liquid extracts gratuitously to all medical men who should ask for them, to be employed in the treatment of any affections. The results obtained have been reported, and a *resume* of these have been published as follows:—

1. Return of the normal condition in locomotor ataxia under the influence of testicular liquid. Out of 342 cases of undoubted locomotor ataxia, 314 were much improved or completely cured. Much the best results were obtained when a large dose (5 or 6 cc.) was injected daily.

2. Other scleroses of the spinal cord. In 117 cases of disseminated sclerosis, 97 of considerable benefit or almost complete cure are reported.

3. Friedreich's disease or other organic affection of the spinal cord. In 2 cases of Friedreich's disease there was very considerable improvement. Sixteen cases of myelitis and other organic affections of the cord have shown progressive amelioration.

4. Cerebral affection (hemorrhage, embolic softening, inflammation, traumatism). In 13 out of 17 cases, paralysis, contractures, more or less disturbed mental conditions have notably improved. The course of general paralysis has not been modified.

5. Pulmonary tuberculosis. More than four-fifths of 67 cases have shown improvement in cessation of cough, of fever, of night sweats, return of strength, of appetite, of sleep, etc.

6. Paralysis agitans. Of 27 cases, 25 have improved, but only 1 complete cure is reported.

7. Cancer. In 103 cases of cancer of the breast, uterus, vagina, rectum, face, lips, nostrils, or other superficial parts, all symptoms have disappeared in spite of the persistence of the tumor. The characteristic tint and other signs of cancerous cachexia, such as weakness, disturbances of digestion, nutrition, etc., hemorrhages, suppurations, ulcerations, local pains, all have disappeared, and, at the same time, sleep and cheerfulness of mind have returned. In certain cases diminution of the tumor is reported.

8. Neurasthenia, hysteria, chorea, and other functional nervous affections. These do not show such good results as do the organic cases. In some cases complete cures have been reported — more especially in chorea.

9. Diabetes and polyuria. Instances of improvement or cure are reported. In some cases better results have been obtained with a mixture of pancreatic and testicular extracts than with either alone.

10. Debility—senility. Much improvement has been got in such cases. In 39 treated by the authors there were only or 54 that were not completely successful.

11. Symptoms have been successfully combated in organic affections of the lungs, heart, kidneys, stomach, liver, intestines, uterus, in Addison's disease, rheumatism, gout, fevers, neuralgia, pseudo-hypertrophic paralysis, etc.

12. So far as the authors know, epilepsy and certain forms of mental disease are the only forms of disease in which this mode of treatment has entirely failed.

In conclusion, it is argued that since the most varied morbid symptoms will disappear under the influence of testicular injections, the nervous system, through an increase of its force by the liquid, must have a more powerful influence on nutrition than has previously been supposed.—*Glasgow Med. Jour.*

## MEDICINE

### Pulmonary Tuberculosis with Especial Reference to its Prophylaxis, Hygienic and Climatic Treatment.

Dr. Otis, states that there are certain general facts which he holds as true, regarding pulmonary tuberculosis which he presents axiomatically as follows:

(1) Pulmonary tuberculosis is, in the greater number if not all cases, a disease of in-door life and impure air.

(2) The first downward step towards pulmonary tuberculosis is impaired general nutrition.

(3) Improper breathing and insufficient lung ventilation may finally result in pulmonary tuberculosis.

(4) Pulmonary tuberculosis is inheritable in the common acceptation of the term.

(5) Pulmonary tuberculosis can be cured or arrested in not an inconsiderable number of cases.

(6) There is no specific for the disease.

(7) The successful treatment is hygienic and climatic; and under hygenic and climatic I include lung gymnastics.

(8) Pulmonary tuberculosis is capable of being cured or arrested in any and all climates, but more readily and surely in some than in others.

Further on in this interesting paper he enumerates a set of interrogatories for the physician to put to himself in his prophylactic endeavors to avert this disease:

(1) Nutrition: Is proper: food of sufficient quantity taken? and is digestion and assimilation good?

(2) Respiration: Is the breathing full and free? and is there good action of the respiratory muscles?

(3) Air: Is pure air and of sufficient quantity supplied? This is of especial importance in sedentary indoor occupations.

(4) Physical exercise: Is sufficient and proper physical exercise taken to ensure good respiration and circulation and proper elimination of waste products?

(5) Situation of dwelling: As to character of soil (damp or dry) and drainage.

(6) Light and sunshine—with especial reference to in-door life: Do working-room sitting-room and bed-room have sufficient light and sunshine?

(7) Clothing and bathing: Is the clothing sufficient and of proper texture? and is bathing sufficiently frequent, not only for cleanliness but to give tone and vigor to the peripheral blood-vessels?

(8) Mental condition: Do worry and a depressed mental state exist?—*Bost. Med and Surg. Jour.*

### Discharge of Ascarides by the Umbilicus.

Dr. Valude reports (*La France Medicale*), the case of an infant which was brought to him on the 4th October, 1891, suffering, it was said, from worms, which were discharged through the navel. The child was a female, aged fourteen months, and otherwise perfectly healthy. No redness or swelling could be seen on examination of the umbilicus, except that the lower half constituted a slight protuberance of the size of a pea, with a moist abraided surface, from which, the mother alleged, the worm made its escape. Pressure on the part established the absence of inflammatory infiltration, but did not cause any worm to appear. After waiting a little while, however, the observer saw one protrude, and he withdrew it himself. Another followed almost immediately. Both were whitish grey in color, eight to ten centimeters long, very lively and active, and perfectly dry; they appeared to come from the lower part of the abdomen.

The child had, from the second week of its life, been partly fed on soup and pap, as the mother's milk was insufficient. In the last week of September, 1891, it began to pass worms by the anus, and on several occasions it had passed seven similar to those above described. On the third October, the lower part of the umbilicus was red and swollen. On the morning of the fourth, a worm emerged from this swelling, and was followed by five others. The child was taken to a druggist, who withdrew three more, and sent the patient to the writer. Some fifteen ascarides were discharged by the navel on that day alone. Santonin had no effect in causing worms to be passed by the rectum; but, a week later, the infant passed five by the anus spontaneously.

On the eighth of November, the umbilicus was thoroughly cicatrised, while the general health continued perfect throughout.—*Glasgow Med. Jour.*

## SURGERY.

### Vomiting of Anesthesia.

Vomiting during anesthesia may be arrested by compression of the phrenic nerve and vagus. Dr. Joos, of the Cantonal Hospital at Winterthur, applies compression with the thumb on the left side, immediately above the sternal end of the clavicle. The hand is held flat on the thorax and the thumb is parallel with the clavicle. In Dr. Joos' experience the vomitond hiccough forthwith ceases. He also suggests that this treatment might be useful for relief of seasickness.—*Canada Lancet.*

## GYNECOLOGY.

### The Significance of Vaginal Discharges.

A leucorrhœa inodorous or of mild odor persisting during the climacteric, accompanied by increasing hemorrhage, is suspicious, and demands investigation. A leucorrhœa profuse, of peculiarly fœtid odor, grumous, excoriating, appearing early or late, during the climacteric, with profuse hemorrhage, is reasonable evidence of cancer in the cervix. A leucorrhœa moderate in amount, ill-smelling (the peculiarly fœtid odor of cancer of the cervix being absent), accompanied by hemorrhage, suggests cancer of the corpus uteri. A leucorrhœal discharge containing material like the washings of meat, is said to indicate sarcoma. A watery discharge, as a rule, occurring during menstruation, odorless, or of little odor, persisting, accompanied by profuse hemorrhage, indicate fibroids; with little or no hemorrhage, polypi. Profuse bloody discharges coming on gradually with declining menstruation, ceasing usually with the menstrual flow, point to fibroids. Persistent profuse discharges of blood occuring spontaneously, arising from sudden exercise or coition, occurring, as a rule, after the menopause, indicate cancer. A gradually increasing amount of menstrual flow is suspicious and needs investigating. "Post-climacteric hemorrhages in a fibroma of the uterus of long standing, form one of the principal grounds for the suspicion of sarcoma." (Borner.) The early recognition of malignant disease is demanded and possible prevention of the fatal exhaustion which accompanies it by the administration of drugs, and the application of those methods which, in a measure, may be supposed to offset the terrific drain on the nervous system; inasmuch as present experience shows that early removal of diseased tissue prolongs life, and the importance of early diagnosis and treatment can hardly be over-estimated. —*N. E. Med. Gazette.*

## ARMY AND NAVY.

U. S. ARMY, FROM NOVEMBER 5, 1893, TO NOVEMBER 11, 1893.

### Promotions.

Captain Edward T. Comegys, Assistant Surgeon, to be Surgeon with the rank of Major, October 20, 1893.

1st Lieut. James D. Clennan, Assistant Surgeon, to be Assistant Surgeon with the rank of Captain, October 29, 1893.

1st. Lieut. Alfred E. Bradley, Assist. Surgeon, to be Assistant Surgeon with the rank of Captain, October 29, 1893.

By direction of the Secretary of War, leave of absence for four months is granted Captain William Stephenson, Assistant Surgeon U. S. Army.

The station of Major Blair D. Taylor, Surgeon, is changed from the old post of Fort Bliss, Texas, to the new post of that name, and he will report in person to the commanding officer of the latter named post for duty.

By direction of the Secretary of War the appointments of William W. Quinton, Thomas S. Bratton, Deane C. Howard, Alexander S. Porter, and William H. Wilson, to be Assistant Surgeons with the rank of 1st. Lieutenants, to rank from October 26, 1893, are announced. They will report in person without delay, to the President of the Army Medical School in this city, for the course of instruction prescribed in General Orders No. 78, A. G. O., September 28, 1893.

## NEWS AND MISCELLANY.

### Swam the Straits of Messina.

Dr. Judson Daland, of this city, who recently went to Italy to investigate into the causes of cholera epidemics, has performed a feat that surpasses Byron's famous swim across the Hellespont. A friend has just received a letter from him telling of his achievement recently in having swam the Strait of Messina, or what was known to the ancients as the whirlpool between Scylla and Charybdis.

"It occurred to me that it would make a good swim," writes Dr. Daland, "more especially as the hotel-keeper, who had lived in the little fishing village called Faro for thirty-two years, told me that no one had ever swam across, in the memory of the oldest inhabitant, although many tried and failed, including the hotel-keeper himself.

"I took to the water at 4.10 P. M. and arrived in good condition on the Italian shore at 6.30 P. M., a distance of six or seven miles. I started from the Sicilian side at Faro, which corresponds to the Charybdis of the ancients, passed the rock called Scylla, and was forced by the powerful current to make a landing at a little village called Riggio, on the Italian shore.

"The entire swin was made without rest or stimulants, and I restricted myself to the breast and side stroke, not using the back at all. I encountered during the swim strong currents, running apparently in all directions, the direction changing every few moments. These currents were at times warm and at others icy cold. There was a high wind and a choppy sea, making it extremely difficult to breathe. I returned to Messina in good condition, and that same evening went to the opera."

## Galenical Preparations

MANUFACTURED BY

## WILLIAM R. WARNER & CO.

MANUFACTURERS OF SOLUBLE COATED PILLS.

FOUNDED 1856

### Standard and Officinal Preparations for Physicians Only.

#### PIL. PHOSPHORUS, DAMIANA ET NUC VOM.

(Warner & Co.)

℞ Ext. Damianæ, 2 grs. | Phosphorus, 1-100 gr.
Ext Nuc. Vom. ⅜ gr.

Med. prop.—Aphrodisiac. Dose, 1 to 2 pills.

Of this combination it has been said: "It re-illumes the fading spark and revives the vital forces."

PER 100, 90 CTS.

#### PIL. ALOIN, BELLADONNA AND STRYCHNINE.

(Warner & Co.)

℞ Aloin.....1-5 gr. | Medical properties—
Strychnine.....1-60 gr. | Tonic, Laxative.
Ext. Belladonna..⅛ gr. | Dose, 1 to 2 pills

Try this Pill in Habitual Constipation.

PER 100, 90 CTS.

#### Pil. Sumbul Comp.

(Warner & Co.)

DR. GOODELL.

℞ Ext. Sumbul . . 1 gr. | Ferri Sulph. Ext. . . 1 gr.
Asafœtida . . . 2 gr. | Ac. Arsenious . . 1-40 gr.

"I use this pill for nervous and hysterical women who need building up." This pill is used with advantage in neurasthenic conditions in conjunction with Warner & Co.'s Bromo-Soda, one or two pills taken three times a day.

PER 100, $1.00.

#### Pil. Lady Webster.

(Warner & Co.)

℞ Pulv. Aloes . . 2 gr. | Pulv. Rose leaves . ½ gr.
" Mastich . ½ gr. | M. Ft. one pill.

This is an excellent combination officinally designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when taken in doses of one pill after dinner.

PER 100, 25 CTS.

BY ALL DRUGGISTS OR BY MAIL.

## THE QUESTION OF FEEDING

The sick, especially where there is a rapid waste of tissue, always interests and often puzzles the Physician. The **FOOD** most desired in such cases is that which contains the greatest amount of nutriment in a concentrated form, easily digested and promptly assimilated.

## RUDISCH'S BEEF PEPTONE

(SARCO PEPTONES)

meets all these requirements, for it will positively be retained by the most irritable stomach when no other food is tolerated. It represents all the nutritive properties of carefully selected Beef in a pre-digested, palatable and soluble form. Equally valuable in hot or cold water, with children or adults. It contains great strength in small doses.

Physicians are requested to write us for free **samples**, pamphlets, testimonials, etc. Mention this journal.

**THE RUDISCH CO., Sole Manufacturers,**
**317 Greenwich St., New York.**

### THE RELATION OF THE OCULAR NERVES TO THE BRAIN.*

CHARLES ZIMMERMANN, M. D.,† Milwaukee.

The course which the ocular nerves take from the brain to the muscles of the eyeball is a very long one, and the number of structures they pass is quite large. Therefore it will be necessary, in order to obtain clearness, to divide them into different sections, of which the division into the *orbital* and *intra-cranial* portions will be the chief one. From the supra-orbital fissure the nerves run along the base of the brain until they reach the brain itself, spreading into the root fibres which end in the ganglia cells of the nuclei, and these are connected by fibres with the cortical centres. Speaking of an ocular palsy, exclusive of diseases of the muscular substance, we have, according to the lesions of the nerve in its different portions, an *intra-cranial*, *orbital*, or *peripheral* paralysis. The *intra-cranial*, is either *basal* or *cerebral*, and the latter may be either *cortical*, *nuclear* or *fascicular*. (Mauthner, *die ursæchl. Mom. der Aug. musk—Læhmungen*). By *fascicular* are meant those palsies affecting the fibres between the cortical centers and nucleus or the root fibres, from which the nerve arises, namely, the fibres between nucleus and nerve trunk. Recken (*Klin. M. f. A.*, 1891, p. 349) divides the ocular palsies into *central* and *peripheral*, according to the degenerative reaction which is missing in the first case. Then a central lesion would compress only the cortical and fascicular between cortex and nucleus, all the rest would be peripheral. After we have ascertained the site of the lesion, we have to find out the nature of it, whether it is due to an inflammatory process, to a degeneration, a separation, or a compression caused by a morbid process, which may be a tumor, produced by a neoplasm, an aneurism, an accumulation of blood from a hemorrhage, an abscess, a meningeal exudation, or to retracting connective tissue pulling or strangulating the nervous elements. Finally, if the cause of the morbid condition creating paralysis of the nerve is determined, for instance, if we know that it is a tumor of syphilitic origin, the diagnosis will be complete. How far we are able to arrive at this our aim may be illustrated by statistics of Leibrecht from Shœler's clinic in Berlin (*C. Bl. f. p. A.*, 1891, p. 371): Among 25,000 eye patients, 312 cases of ocular palsies were observed. Seventy of these were under sufficiently long treatment for the collection of careful records, but despite thorough examination by neurologists and long continued observations, the etiology could be elucidated only in 64 per cent. Thirty-six per cent., that is one-third, remained unexplained. Hutchinson has reintroduced the term *ophthalmoplegia*, used by Von Græfe in 1869, and calls it internal, if all the muscular structures are within the globe, and external, if all or the most muscles moving the eye ball are paralyzed. Mauthner

*Read before the Wisconsin State Medical Society, 1893.

†Ophthalmic and Aural Surgeon to St. Mary's and Emergency Hospitals.

changed them into the words *interior* and *exterior*, in order to avoid confusion with paralysis of the internal or external recti, and uses ophthalmoplegia, if muscles of one eye, supplied by different nerves, or if muscles of both eyes are paralyzed.

In searching for the site of the lesion, we must study the cerebral origin of the ocular nerves, especially the location of the *nuclei*. The nucleus of the third nerve, being the most complicated, has been investigated with particular care in the last few years. In 1878, Hensen and Voelckers (*v. Graefe's Arch.* 24, 1, p. I.) found, by stimulating different parts of the brain of dogs with the faradic current, that the nucleus of the third nerve occupies the posterior portion of the floor of the third ventricle, commencing above the mamillary bodies and the floor of the aqueductus Sylvii, to the region of the posterior corpora quadrigemina. The most anterior—the nucleus of the ciliary muscle followed by that of the sphincter pupillæ, lies on the floor of the third ventricle above the mamillary bodies. At the border of third ventricle and aqueduct, below the posterior commissure, are the centers of the rectus internus; on the floor of the aqueduct those of the rectus superior and levator; below the anterior pair of the corpora quadrigemina that of the rectus inferior, and below the posterior pair that of the inferior oblique. They state, however, that the position of the three latter is not absolutely certain, on account of the possible errors arising from the insufficient isolation of the faradic current they used in their experiments. In 1881, Kahler and Pick (*Prag. Z. f. h.* 11. 4., p. 301), from two pathological anatomical investigations observed the same in regard to the interior muscles of the globe, namely, that their nerves originate from the most anterior root fibres of the oculo-motor nerve, but in regard to the exterior muscles, they found in a case of paralysis of levator, rectus superior and inferior oblique, the lateral bunch of the posterior root fibres damaged, the medial intact, which reversely, in another case of paralysis of the internal rectus, was degenerated. They located the root fibres of the rectus inferior also in this medial portion. Starr (*Jrl. of Nervous and Ment. Dis.*, 1888) adopted the same scheme after an analysis of twenty cases. In 1882 and 1883, vonGudden investigated the nucleus of the third nerve in rabbits with his degeneration experiments. After removal of the corresponding muscles of the eye and tracing the secondary degeneration of the nerve to its centers, he discovered that each third nerve has two nuclei, a ventral and a dorsal; the former, consisting of two clusters, is the origin of the nerve of the same side, the latter supplies the opposite nerve with crossed fibres. Edinger, Westphal, Darkschewitsch and others worked on the same subject, but the most detailed description was given by Perlia (*v. Graefe's Arch.*, 35, 4) in 1889. He formulated an anatomical picture of the oculo-motor nucleus by numerous sections of the fetal and adult human brain in frontal, sagittal and horizontal directions. It has the shape almost of a triangle of broad base, with the greatest sagittal diameter of about ten m. m., and is divided into a larger posterior and a smaller anterior portion. The chief group contains four pairs of lateral large-celled nuclei, a single large-celled central and one pair of the small-celled nuclei of Edinger-Westphal. The anterior portion consists of a lateral and a medial cluster, so that all together eight nuclei form the center of the third nerve. He found crossing of the root fibres only of nucleus five and of the fourth nerve, so that Knies takes this as the center of the inferior oblique, which acts in the same sense with the obliquus superior of the other eye.

Pflueger (*v. Græfe's Arch.* 36, 4,) adopts this view of Knies in explaining a nuclear palsy of both obliqui superiores and the right obliquus inferior. Although Perlia thinks that we have not succeeded as yet in proving with certainty by pathological anatomical investigations the connection between any branch of the oculo-motor nerve and its nucleus, Knies (*Arch. f. Augenh*, 1891, 23, p. 45) believes that it can be done with a good deal of certainty by aid of the schemes arrived at by Hensen and Vœlckers, Kahler and Pick, and Starr, but he places the nucleus of the sphincter before that of the ciliary muscle. Perlia advocates, however, the assumption that the posterior longitudinal fascicule connecting the oculo-motor center with the medulla oblongata, forms a connecting link between the nuclei of the third, fourth and

sixth nerves. He detected another system of nervous fibres reaching the oculo-motor center from above and joining it with the reticular substance of the foot of the peduncle, the function of which is not known yet. Perhaps the cortical fibres of the third nerve originate from them according to Obersteiner (*Anleitung, etc.*, 1892, p. 376). The larger portion of the root fibres runs in a lateral direction to the posterior longitudinal fascicles, forming thicker branches beyond them; the remaining ones, mostly from the dorsal nucleus, run downwards to the median line, in which they cross to the other side. Siemerling (*Chron. progr. Læhmung der Aug. musk.* 1891), who examined microscopically the nuclei of the ocular nerves in eight cases, which had been observed very closely clinically, could not decide the question in regard to the crossing of the root fibres and the function of the lateral and medial groups. But he places with some probability the center of accommodation and iris in the anterior, and those of the muscles raising the eye-ball in the posterior lateral nuclei. As a new discovery he describes a congeries of ganglia cells in the posterior longitudinal fascicle on the level of the nucleus of the fourth nerve, which he always found intact when ptosis was absent, so that it probably presents the center of the levator. Mendel (*Berl. Klin. W.* 1887 p. 913) localized the center of the upper, or so-called ocular facial nerve, in rabbits and guinea-pigs in the posterior portion of the oculo-motor nucleus. He removed the frontal muscle and the upper and lower lid, in order to destroy the orbicularis completely, and found later atrophy of the posterior portion of the oculo-motor center, but the facial nucleus in the medulla intact. He concludes that the fibres of this nucleus, representing the ocular portion of the facial nerve, run in the posterior longitudinal fasciculi to the nucleus of the facial nerves and unite with peripheral fibres, recognizing in this arrangement an analogy with the spinal nerves noticed in poliomyelitis, that in the center fibres of muscles of associated function, are united fibres terminating in entirely different peripheral nerves, so that in man perhaps the same formation of the facial nerve exists.

This theory would easily explain the fact that in bulbar palsy only the lower fascial branches participate, since the bulbar palsy does not extend so far upward as to reach the nucleus of the oculo-motor and, consequently, of the upper fascial nerve. Birdsall (*Jrl. of Nerv. and Ment. Dis.*) observed a case of ophthalmoplegia exterior with paralysis of the muscles supplied by the third nerve, in which the excitability of the orbicularis and frontal muscles was impaired. This would also correspond to Mendel's hypothesis for the human brain, but the proof by a post-mortem examination was wanting.

The origin of the fourth nerve is close behind the oculo-motor center, and, in frontal sections, below the anterior portion of the posterior part of the corporo-quadrigemina. The root fibres run backwards to the anterior velum medullare, where most of them cross to the other side. The nucleus communicates with the brain by the raphe, with the anterior corpora quadrigemina and the posterior longitudinal fascicle. In Siemerling's (*C. Bl. f. A.* 1891, p. 247) opinion it is not a continuation of the oculo-motor center, at least not as was generally accepted so far.

The nucleus of the sixth nerve lies in the dorsal region of the tegmentum next to the facial knee, and contains large star-shaped cells from which the root fibres develop at its lateral portion, run in a dorsal direction in circles and pass through the region of the tegmentum. A part of them take a median course and cross. The fibræ arcuatæ connect it with the brain, crossing in the raphe, and go in a vertical course to the pyramidal tracts. Other fibres communicate by the posterior longitudinal fascicles with the oculo-motor center.

The results of the latest researches on the nuclei of the ocular nerves are given in some detail, as of the cerebral palsies the nuclear is the most important. According to Mauthner the progressive paralysis of the ocular muscles in most cases is caused by a nuclear lesion. Ophthalmoplegia exterior must be nuclear under all circumstances (if not orbital). Therefore the integrity of the interior muscles of the eyeball is a very valuable symptom in the diagnosis of nuclear paralysis. This can happen only if the lesion attacks the branches of the third nerve at a place where they are separated, and that is in the nuclei. The explanation of this peculiar fact, that in such a

small range as the center of the oculo-motor nerve some nuclei should be diseased, the others not, was given by Heubner, (*C. Bl. f. d. med. W. S.* No. 52, 1872). He proved that at the base of the brain the small arteries form no anastomoses and are terminal vessels supplying a very limited portion of the brain substance.

The ramus communicans posterior supplies only the nuclei of the sphincter iridis and ciliary muscle, so that the arterial area of these is perfectly isolated from the other oculo-motor centers. Therefore ophthalmoplegia interior must be nuclear too. But clinical experience has shown that both forms may occur—simultaneously or one after the other, and that nuclei of other cranial nerves may be involved if the morbid process, affecting at first only a small portion of the gray substance in the walls of the third ventricle, extends forwards or backwards. In this way a disease of the nuclei of the exterior muscles may reach the optico-pupillary center in the walls of the third ventricle and abolish the reaction of the pupil to light, without damaging the center of the sphincter, or that of accommodation. Or the center of the sphincter may be destroyed with immobility of the pupils, but the accommodation be preserved. Or the latter may be reached also, so that we have a total paralysis of the third nerve. Then the nuclear lesion has to be diagnosticated from the complications. In other cases the degeneration starting from the most anterior nucleus, being that of accommodation, and traveling downwards, may involve the centers of all the following cranial nerves and finally reach the anterior (motor) cornua of the spinal cord, resulting in progressive muscular atrophy. Another form of nuclear palsy is uncomplicated paralysis of the oculo-motor nerve with myosis described by Fontan (*Mauthner* l. c.) in a case of nicotin intoxication, the nicotin paralyzing the nuclei of the exterior and at the same time irritating the nuclei of the interior muscles.

Paralysis of the third nerve with simultaneous maximal dilation of the pupil may be due to basal or nuclear lesion, by paralyzing the oculo-motor nerve and irritating the more resistant sympathetic fibres by compression, either at the superior orbital fissure or in the walls of the third ventricle, the irritation of which caused mydriasis in the experiments of Hensen and Voelckers.

Although anatomical researches in regard to the ocular nuclei have proven a partial crossing of their fibres, so that a unilateral nuclear paralysis would not be very probable, Mauthner infers from clinical observations that the ocular nerves of each eye have all their nuclei on the same side, and that moncular total ophthalmoplegia is caused by a successive disease of the nuclei of the same side, as in the scheme of Kahler and Pick. Eissen (*Kl. M. f. A.* 1890, p. 277) supports this assumption in opposition to Boettiger (*Arch. f. Psych.* 1889). An isolated or partial palsy of any ocular muscle, as observed in locomotor ataxia, disseminated sclerosis and progressive paralysis of the insane, are nuclear. They may be very slight and transient, and, as for instance, mydriasis may be the precursor of these diseases for many years.

The nuclear character of isolated palsies of the exterior muscles may sometimes be determined from the accompanying symptoms. In diabetes they are probably caused by hemorrhages in the nuclear region. Somnolence is another important symptom of nuclear palsy. Mauthner (*Wein. med. w.* 1891, No. 26 and 27) places the seat of sleep in the gray matter surrounding the central ventricle, in the upper region of which the nuclei of the third nerve are situated, and describes ptosis and paralysis of the internal rectus as the focal symptoms of sleep. Headache and pain in the eye may be present or absent in nuclear palsy. Wernicke and Mobius (*Berl. K. W.* 1884, No. 38) attribute it to irritation of the descending root of the fifth nerve which contains the sensitive fibres of the eye and the dura mater. The manner in which the paresis sets in is characteristic for a nuclear lesion. Before it is complete, the movements are slow, as if in wax, and the palsy can be overcome by an energetic mental effort; or it changes in the course of a day, the ptosis, for instance, is less marked in the morning than at night. This shows clearly the origin in the nuclear cells; if not entirely destroyed, they can be influenced by an impulse, which would be impossible if it were in the nerve itself and the conduction interrupted. The nuclear palsies are not associated as

nuclear paralysis of both abducentes was observed. If they last for a time, no double images are complained of. Very different morbid processes may cause nuclear paralysis. Congenital ptosis, for instance, with functional impairment of rectus superior and obliquus inferior is due to a malformation in the nucleus (*Mauthner* p. 377), traumatic hemorrhages into the nuclei, tubercles and compression of the medulla oblongata and of some ocular centers by caries and tumors of the vertebræ. The most common causes are ependymitis, with secondary sclerosis extending into the gray substance around the ventricles, multiple sclerosis and atrophy of the ganglia cells. The nuclear ophthalmoplegia may be congenital or acquired in the first years after birth without any other disturbances, or it may develop in adults and remain stationary without other cerebral symptoms. But it may be complicated with headache, paralysis of other cranial nerves, bulbar palsy, locomotor ataxia, progressive muscular paralysis and mental diseases. In cases of acute or sub-acute development it may be fatal by its complications, or heal and recur, or remain stationary.

Our knowledge of the cortical lesions of the ocular muscles is still very limited, since the cortical centres are not explored beyond doubt. What we know of them is mostly obtained from experiments on animals, consisting in the stimulation of the cortex by faradic currents. Hitzig placed the cortical center of the ocular muscles in the frontal lobe, Hensen and Voelckers in the temporal, Ferrier in the angular gyrus and Munk in the occipital lobe.

Recent experiments of Munk (*C. Bl. f. A.* 1890, p. 149) on dogs confirmed Schæfer's investigations on monkeys, that stimulation of the visual center with weak faradic currents elicits associated ocular movements of the opposite side, the eyes turning downward if the anterior, and upward if the posterior area of the visual sphere is stimulated. Ocular movements never occured if a spot outside the visual sphere was irritated. Munk explains these facts by the supposition that the fixation of the eyes is instituted by perceptions of light, by which stimulation of the radiant fibres of the corona ciliaris is propagated to subcortical portions of the brain. These fibres govern the involuntary movements of the eyes which we perform in order to find the right fixation of objects we noticed only indistinctly before, and are to be considered as congenital reflexes, as the lowest visual reflexes are dependent upon perception of light, not on visual impression. They are a great help for the quick and reliable preception of the visual field. The fibres of association which connect the visual spheres with the cortical motor centers of the ocular movements, govern the higher visual reflexes. Knies, (*l. c.* p. 24.) assumes two different cortical spheres for the voluntary innervations of the ocular muscles. *First*, the visual sphere for the voluntary movements of the eye, convergence and accomodation, and *second*, the so-called motor cortical region of the levator. He acknowledges the involuntary character of the ocular movements obtained by Schaefer and Munk, but they run in the same tracts in which the voluntary impulses to ocular movements are physiologically conducted to the muscular nuclei. All voluntary ocular movements starting from the visual cortex are conjugate and tend to binocular fixation. The visual cortical center of each side governs chiefly the voluntary conjugate movements of the eyes to the opposite side. The area of the visual sphere corresponding to the macula is the cortical center of the voluntary convergence and accommodation of a fixed object and it may start innervations for voluntary movements in all directions. Each visual sphere is connected chiefly with the nuclei of the third and fourth nerve of the same, and with that of the sixth nerve of the opposite side. All voluntary ocular movements are conjugate, therefore all disturbances of them are conjugate.

These quotations will sufficiently show how difficult a definite diagnosis of cortical or fascicular paralysis will be, so far as the fibres between cortex and nucleus are concerned. If a paralysis of the exterior muscles supplied by the third nerve is associated with contra-lateral hemiplegia, the lesion must be fascicular and is located in the pedunculus cerebi, in which the exterior fibres coming from their nuclei behind and the interior fascicles from in front are still separated, as proven by two post-mortem examination of Kahler and Pick. If exterior and interior muscles are affected, the focus must be near the

exit of the nerve where they unite, or it may be basal and be caused by two different lesions. Paralysis of the sixth nerve with contra-lateral hemiplegia is due to a focus in the pons. In regard to the differential diagnosis between these three kinds of cerebral palsies from the basal, we have only one symptom which is absolutely certain and that is the integrity of the interior muscles if the exterior are paralyzed. This never happens in basal lesions. The recurrent paralysis of the oculo-motor nerve in most cases is basal. It is characterized by the fact that only one oculo-motor nerve is totally paralyzed, and that each relapse affects always the same nerve, never that of the other side. It heals for awhile, or becomes less in intensity until, after weeks, months, or a year, a new attack occurs, usually commencing with hemicrania and lasting from one day to several weeks or months. It is always acquired in infancy, most likely by an injury of the base of the skull from a trauma of the head, happening so often in children, and subsequently gradually developing pachy—or lepto-meningitis near the trunk of the oculo-motor nerve. The relapses are explained by transient increased hyperaemia (for instance, in females at the time of the menses). Pel (*Berl. K. W.* 1890, 1,) observed a case of recurrent partial paralysis of one third nerve, of nuclear origin proven by the integrity of the interior muscles, in the first stage of locomotor ataxia, relapsing seven times.

The isolated bilateral paralysis of the third nerve may be nuclear, or basal from compression by a tumor or artery at the base, or from meningitis. Both sixth nerves may suffer by a nuclear disease in the fourth ventricle, by a basal affection at the posterior margin of the pons, or by symmetrical compression in the cavernous sinus by tumors from increased intracranial pressure. Affection of both fourth nerves may be in the anterior velum medullare and therefore fascicular, or it may be nuclear, as Pflueger observed in a case.

Sometimes it is very difficult to differentiate a nuclear from a basal unilateral multiple paralysis of cranial nerves, and then the condition of the olfactory and optic nerves becomes very important. Homonymous hemianopia in such cases may be nuclear or basal, as the lesion may be situated in the thalamus opticus and then be nuclear, or in the tractus opticus and then be basal. Amaurosis of the eye of the same side alone or with temporal hemianopia of the other eye can be only basal. In the first case it can only happen by compression of the optic nerve at the base after it has left the chiasm, and in the second case the optic nerve and tract of the affected side are damaged. The affection of the olfactory nerves in multiple paralysis of cranial nerves shows generally a basal cause, but in nuclear paralysis anosmia may be due to a disease in the bulbus olfactorius.

Nuclear and basal palsies may occur simultaneously from the same cause—for instance by a tumor of one hemisphere paralyzing the anterior cerebral nerves by pressure at the base and by hydrocephalus of the fourth ventricle compressing the nuclei at its floor. Bilateral progressive paralysis of cranial nerves is in most cases nuclear, the diagnosis resting chiefly on the condition of pupil and accommodation. Blindness of both eyes without ophthalmoscopic changes, or with simple atrophy of optic nerves in such bilateral affections, may be nuclear as proven by autopsy, or basal caused by strangulation of retracting tissue from a partial chronic basilar meningitis. The peculiar fact was observed in autopsies, that the nerves at the base, even if apparently destroyed, when perfectly flat by compression or imbeded in inflammatory growths or tumors, sometimes do not show any degeneration of their fibres, so that their functional disturbance must be explained by an ischemia of the vessels of the nerves.

The causes of basal palsies may be of various kinds (according to Mauthner's synopsis): Hemorrhages; circumscribed pachymeningitis near the nerve trunks; meningitis of the cortex and the base, the latter mostly tubercular in children—therefore in children double vision from paralysis of an ocular muscle gives a very bad prognosis; abscess of the brain, especially of otitic origin; disease of the basal arteries, as aneurism; arteritis obliterans by want of blood supply to the nerves; syphilitic products and neoplasms growing around and into the nerves. The nerves themselves may be the seat of neuritis, of gummous and tubercular interstitial neuritis and perineuritis; lymphomatous swelling in cases of general lymphomatous and gray degeneration following atrophy of the nuclei.

# COMMUNICATIONS.

## THE TREATMENT OF ACUTE PNEUMONIA WITH ICE AND SUPPORTING MEASURES.*

THOMAS J. MAYS, A. M., M. D.†

Acute pneumonia is a disease which we all recognize. Its symptoms and physical signs, its course and duration, are constant and characteristic; yet, strange to say, its treatment is as variable and vacillating as its death-roll is long and appalling. In the city of Philadelphia alone fifteen hundred lives are annually sacrificed to this disease. Is this frightful mortality inevitable, or is there a way to escape it? I believe that it can be materially lessened, but before this can be done we must realize the shortcomings and the mischievous tendencies of professional thought on this subject at the present day. I believe that the want of uniformity in the therapeutics of this disease is partly traceable to the prevailing but mistaken theory that pneumonia, like measles and smallpox, is a self-limited disease, and therefore beyond the touch of successful active medication. Then again, the general skepticism of this age has invaded the field of therapeutics and has cast a gloom of doubt on the remedial effects of the long-honored articles of our materia medica. Both of these tendencies in connection with the fact, which has been shown over and over again, that the practical results of the let-alone treatment of pneumonia are superior to those which are obtained when the disease receives the active routine treatment of days gone by, have brought the therapeutic art into undeserved discredit, and have sown broadcast a belief that the less active the treatment is to which pneumonia is subjected the better it is for the patient. In accordance with this view the disease pursues its natural course in spite of any treatment, and all that can be done is to stand by and watch and treat any incidental danger which may develop.

What ground is there, then, for believing that the pneumonic processs is self-limited, and that the therapeutic art is powerless in making a local impression on it? So far as I can see, there is no more reason for regarding pneumonia self-limited than there is for considering any other ordinary acute disease in the same light. All diseases of this kind are limited in duration, but there is no inherent limitation, in the same sense as there is in small-pox or measles. Let us say pneumonia suddenly attacks a single lobe of a lung, and in the course of three or four days it suddenly ends in crisis, and every vestige of the disease disappears. Its sudden onset and termination in many instances lead us to infer that pneumonia is due to the absorption and explosion of a specific poison which exhausts its energy in a few days, and to see an analogy between its behavoir and that of smallpox. On the other hand let us suppose another case of pneumonia involving the same lobe of the lung. In about three days the temperature suddenly drops to within a degree of the normal line, and a favorable termination is anxiously looked for, but instead of this, the temperature rises higher, and on physical examination it is now found that the whole of the adjoining lobe is implicated in the process. A similar succession of events may take place in case another lobe or part of a lobe becomes involved. These phenomena are familar to every practitioner, and yet can anyone say this is definite proof of the self-limitation of pneumonia? Has anyone ever heard of smallpox or measles attacking the body by piecemeal, first invading one area, then another, and so on? Is it not more probable that the duration of the pneumonic process is chiefly governed by the length of time which it naturally takes for the fibrinous exudation to undergo fatty degeneration; and that when the fibrinous deposit occurs successively in different lung areas the disease will be more protracted on this account than if it confines itself to the area which became primarily involved?

* Read before the Phila. Co. Med. Soc., October 25, 1893.

†Professor of Diseases of the Chest in the Philadelphia Polyclinic, and Visiting Physician to the Rush Hospital for Consumption.

Moreover it is my firm conviction that the prevailing impression that the pneumonic process cannot be controlled or restrained by means of active medication, rests on an equally insecure foundation. I am not rash enough, however, to assume that any form of treatment can be devised which will always insure against death from pneumonia, but from recent experience I believe that a mortality of 20 per cent., which is the usual death-rate, is too high, and that this may be materially reduced. I also firmly believe that this reduction in the mortality cannot be brought about exclusively through internal medication, feeding, or stimulation, valuable as these measures are. The profession fully realize the vital importance of sustaining the strength of the patient thoroughout this disease, and practically this part of the treatment is carried out with very desirable results. Far above the efficacy of all these measures, however, stands ice, or ice-cold water—the local application of which has the undoubted power of subduing and of circumventing the inflammatory process in the lung.

I base this favorable opinion on the results which were brought out in my collective report on "Ice in the Treatment of Acute Pneumonia." This paper consists of the condensed histories of fifty cases which were treated locally with ice or cold applications, and which were reported to me by professional friends, or were collected from the literature on the subject, or came under my personal observation. Out of the entire number, two died, making a death-rate of 4 per cent. Additionally I refer to one hundred and six other cases of pneumonia treated in the same way by Dr. Fieandt, a physician of Finland, who had a mortality only of 2.82 per cent.—giving us a death-rate among all of these cases of 3.2 per cent. Moreover, since the appearance of my paper I have succeeded in securing a number of other reports of cases thus treated, which continue to maintain the favorable impression made by the ice treatment in the first report, and which I hope to include in a future contribution on this interesting problem.

Asides from the fact that both of the cases which died among those reported in my list were suffering from probable incurable disease when they were smitten with pneumonia, and were, perhaps, on this account not the most impartial test for any new remedy, it is quite evident that the total showing is still better than appears on the surface. Great weight must, I think, be laid on the fact that these cases emanate from fourteen independent observers, half of which number report only one case each. This excludes largely the existence of a personal factor —an attribute and a power which grows out of accumulated knowledge and experience and gives its possessor a certain advantage over those less equipped in this direction—and goes far to demonstrate that the curative effects of ice applications do not depend on any very special artistic skill of the medical attendant.

I am often asked whether ice is as efficacious in catarrhal as it is in croupous pneumonia. On theoretic grounds one would be led to believe that it is of greater service in the latter than in the former variety, because the whole inflammatory process is more ephemeral and entails less organic change of the lungs in that form. While my first cases in which the ice was used were exclusively those of the croupous variety, my later experience has taught me that this measure has a similar beneficial effect in catarrhal pneumonia, provided it is pursuing an acute course. This is fully demonstrated by a number of the cases contained in my report, notably by some of the cases which were treated by Dr. Lees, and also by the one reported by Dr. Franklin. Indeed, I believe it is impossible sometimes to discriminate between croupous and catarrhal pneumonia during life, when the latter pursues an acute course, and especially when it takes place in infants or small children.

In what special manner should the ice be employed? For want of a better method, the front, side, and back of the affected area are surrounded with rubber bags filled with ice and wrapped in towels. The number of bags which are needed depends on the size of the area which is involved. If this is small only one or two bags are necessary, but in cases where an extensive area is affected I have applied as many as six and seven, which suffice to cover the whole chest. They are allowed to remain until the temperature becomes nearly normal. Very often it is found that the application of the ice to an affected spot is immediately followed by a marked lowering of the temperature,

and improvement in the physical signs in the part. In a very short time, and perhaps in the midst of this amelioration, the temperature rises again, and the patient feels less comfortable than before. Further examination shows that the disease has invaded a new and probably an adjoining territory. Removal of the ice-bags to the fresh spot, or the application of new ones, will again be followed by improvement. This creeping feature of pneumonia must always be borne in mind, and followed up until it ceases.

One difficulty in the use of the ice-bags is to keep them constantly applied to the chest in restless patients, and this has led me to look into the feasibility of making a hollow tin jacket, which adapts itself to the chest, and through which a constant current of ice-cold water may be passed. Such an apparatus I have in contemplation, and when it is perfected I think it will add much to the effectivenesss of the application, and will also be a greater convenience to the patient.

The subject of diet demands the most serious consideration of the practitioner, whose aim should be to administer food of the most nourishing character and in the most concentrated and digestible form. In other words, he should strive to give the stomach as little work to do as possible, and at the same time maintain the nutrition of the patient at the highest point. For this reason two ounces of fresh beef-juice pressed out of round steak should be given alternately every hour and a half or two hours, with eight tablespoonfuls of milk, one of whiskey, and one of lime-water. Beef-powder, and nutrient wine of beef-peptone may also be given.

So far as internal medication is concerned, I would say that strychnine stands first in this respect and should be given unstintedly. Adults should receive $\frac{1}{25}$ or $\frac{1}{20}$ of a grain twice a day hypodermatically, and $\frac{1}{25}$ of a grain by the mouth every four hours, until there is a manifestation of toxic symptoms, such as an increase of the reflexes, especially of the lower extremities. A quarter of a grain of morphine is to be given subcutaneously in the evening to produce sleep. An ice-bag to the head will also help to allay cerebral excitability and restore quiet. Evacuation of the bowels should be secured by the administration of small doses of calomel and sodium bicarbonate.

When cyanosis and difficult respiration become very marked inhalation of oxygen must be employed. The patient may inhale the gas out of an ordinary-sized rubber bag through a suitable mouth-piece which is attached to it. The amount of oxygen which must be given in a case is entirely dependent on the severity of the symptoms, but it is a good rule to push it until the lips and finger-nails assume a more healthy appearance, and the breathing becomes less oppressed, and to give it as often as it is necessary to suppress these symptoms.

Now when we compare the results of the ice treatment of pneumonia with those which are obtained from the prevailing treatment, it will show very much in favor of the former mode of treatment. Thus the mortality of 1012 cases in the Montreal General Hospital was 20 per cent.; while in the Charity Hospital, of New Orleans, it was 20.01 per cent. From 1822 to 1889 the mortality from pneumonia in the Massachusetts General Hospital was 25 per cent. Dr. Hartshorne estimates that the death-rate from this disease in the Pennsylvania Hospital, this city, was about 31 per cent. during the years of 1884, 1885, and 1886. A comparison of this mortality-rate with that which has been derived from the treatment advocated in the present paper, shows that the latter produces results which are at least 75 per cent. better than those which are obtained when the cold applications are not employed. I know that the number of my cases is rather small to draw such promising deductions, but from my experience since they were published I am encouraged to believe that this form of treatment will not only maintain its excellent reputation, but will grow in increased favor on closer acquaintance.

---

NEWFOUNDLAND dogs are to be employed to rescue the persons who fall or throw themselves into the Seine. The dogs are to be housed upon barges anchored in the river. The skill with which these dogs recognize the falling of persons into the river, and the unerring certainty with which they reach the body by the most direct route and seize it at the proper place and swiftly bring it to the barge or shore, are matters of marvel to all observers.—*American Lancet.*

# OPERATIVE PROCEDURES FOR CARCINOMATOUS TUMORS OF THE BREAST.*

J. McFADDEN GASTON, M. D.,† ATLANTA, GA.

The high estimate placed upon the preservation of the mammary gland is attested by the commendable pride of every fair maiden in the development of this part of her organism and by the practical concern of every mother in the due performance of the function of lactation.

Not only from an esthetic standpoint but from utilitarian considerations, the mammary gland is recognized as entitled to a prominent place in the physical structure of woman, and anything which tends to induce diseases of this organ appeals strongly to the physician and surgeon for relief. It becomes us, therefore, to use all diligence in the prophylactic and curative appliances directed to it.

While the mammary gland is liable to injuries of various kinds and to inflammation in connection with its functions, there is a special proclivity to disorders of a graver character, characterized by developments of a malignant kind in its structures.

The mammary gland is peculiarly constituted in the human female and its anatomical relations to the lymphatics render it more liable to complications with the neighboring ganglia, under inflammatory processes, than occurs in any other part of the organism. There are physiological sympathies of this gland with other viscera which indicate a deep seated and intimate correlation between them, but we are interested now especially in the investigation of the link which binds this structure to the general physical system. The involvement of the mammary gland in carcinoma is most frequently associated with marked impairment of the general health, and earlier or later that condition known as cachexia is developed, so as to become characteristic of the progress of a carcinomatous disorder. There is some plausible ground for doubt as to cause and effect in the local and general manifestations of carcinoma, and hence a question in regard to the circumscribed area of the disease at the outset in the tissue of the mammary gland. It is held by most observers that cancer of the breast is primarily a strictly local trouble and if removed at an early period, must be eradicated. But either the tumor has from the outset a proclivity to reproduction, or comparatively few cases are operated on sufficiently early to arrest their progress, as it is well known that a return of the neoplasm is the most frequent result of operations for the removal of carcinomatous tumors of the breast. This holds in regard to the complete as well as the incomplete mode of operating in these cases, and in those patients, without enlargement or induration of the axillary glands, there does not appear any good and sufficient reason for the invasion of this region by the knife. There are no indications of trouble beyond the limits of the breast and under such circumstances, it must prove very difficult, if not quite impracticable, to identify the lymphatic glands and remove them. If it was simply a matter of indifference as to the effect of this complete operation upon the patient, each operator might cut and slash to his heart's content in the axillary and in the clavicular space, but when it adds to the traumatism in a way to damage the prospects of recovery, it certainly should be reserved for the removal of diseased lymphatics. Even in a case of involvement of the ganglia in the clavicular space, it is problematical whether the shock of enucleating them may not overbalance any advantage which can accrue from their removal.

In the legacy left to the profession by Dr. Douglas Morton, in answer to the question, "How should we operate for mammary cancer and when?," it is held that the "completed operation" is not only far more dangerous than the old one, but in an important sense is still incomplete after all. As it is usually done, the axillary glands and some tissues about them are removed. The intervening lymphatic ducts that may be full of cancer cells,

* Read before the Southern Surgical and Gynecological Association at New Orleans, November 15, 1893.

† Professor of Principles and Practices of Surgery, Southern Medical College, Atlanta, Ga.

especially at their valves, are at best only partially removed; the alveolar buds that shoot out from every gland from the moment it enters the process of becoming fixed are cut or torn through, causing cancer cells to be scattered over the surface of the wound soon to become fixed as new foci. Furthermore the supra- and sub-clavicular glands that in many, perhaps most of the cases, become infected sooner or later, are in the "completed operation" as it is ordinarily done, left intact; even Gross, a most earnest advocate of this operation, removes these glands only when they are palpably enlarged. Butlin calls it a "surgical blunder."

In order to examine systematically the conditions that bear upon "clearing out" the axilla, Dr. Morton claims that all mammary cancer subjects may be divided into four classes. (1) Those in which the disease has not only infected the axillary glands but by metastasis or otherwise has involved the internal tissues and organs; (2) those in which these glands have become infected, but in which the disease has gone no further; (3) those in which metastases have occurred without infecting the glands; (4) those cases in which the disease is as yet limited to the mamma. He goes on to say that the cases of the first class are plainly not operable. In those of the second, if clearing out the axilla and removing every gland in the whole neighborhood of the diseased breast and the tissues around them, as well, were to complete the operation as the term implies, it would certainly be justifiable, provided the mortality after this procedure is not too great.

The statistics of local recurrences given by Gross in 1888, are quoted by Morton as follows:

Of 409 cases, partial or total extirpation of mamma, without glands, was done in 96 cases.

Recurrence in or near the cicatrix, 46 cases, being 47.91 per cent.

Recurrence in cicatrix and glands, 31 cases, being 19.79 per cent.

Recurrence in glands alone, 19 cases, being 32.29 per cent.

Of amputation of breast with removal of glands, 313 cases.

Recurrence in or near cicatrix, 235 cases, being 75.08 per cent.

Recurrence in glands alone, 38 cases, being 12.14 per cent.

Recurrence in both places, 40 cases, being 12.77 per cent.

These figures, Morton believes, show the impossibility of doing any operation that deserves to be called "completed" after the invasion of the axilla has taken place. They show, too, that the number of local foci so far from being diminished, is certainly very much increased. These facts, taken with the other very important fact that the immediate mortality after the "completed operation" is double (accordingly to the statistics of Butlin) that after the incomplete, seems to Morton, to utterly condemn the former as a life-saving measure in this class of cases.

In the above division, the third class of cases, in which metastatic tumors have occurred, without antecedent glandular involvement, are clearly not amenable to operation.

The fourth class embraces those cases in which the cancer is as yet strictly local, and hence eradicable by operation.

Morton thinks that after the axillary glands have once become involved it is highly improbable that the disease can be eradicated by any surgical procedure.

A point of great moment, as to the extent of operative precedure, pertains to the leaving of any portion of the mammary gland, when only partially implicated in the carcinomatous growth. The esthetic element should never enter into the decision of such a vital question as the arrest of carcinoma, and whenever a breast is the seat of a malignant tumor, whether wholly or partially involved, there should be no hesitation about removing the entire glandular structure. If a part of the mammary gland only seems to be involved and it is evident the knife can be carried outside of the neoplasm into the apparently sound tissues of the breast, there is every reason to believe that if any portion of the gland is left it may become the seat of disease and that recurrence will most likely follow the operation. On the other hand, an entire ablation offers better prospects of success.

The preservation of such part of the skin as may serve to cover up the denuded surface of the thoracic wall, after removal of the breast depends upon the extent to which the cutaneous covering of the tumor is adherent, and consequently involved in the disease. It may be that the direction of the incision will influence

materially the capacity for bringing the edges of the skin together, owing to the looseness of the attachment and the elasticity of the tissue in one direction being greater than in another so as to favor traction. In most cases saliency of the tumor admits of making a double elliptical incision, so as to take away the adherent cutaneous covering with the diseased breast, and all the skin which is loosely attached by cellular tissue may be safely preserved to cover the wound without undue traction. Retentive ligatures, at the distance of an inch or more from the margin, may be inserted at the points of greatest tension, and between them broad strips of adhesive plaster may be placed to secure union of the edges. If cancer of the breast returns after removal it is inculcated by most writers to operate again and again, so often as the growth appears, and it is held that thus the life of the patient is prolonged. At the present day, when a patient is free from suffering by an operation, under the influence of anesthesia, there can be no objection to the repetition of cutting while the patient is disposed to submit to the knife. But a patient whose breast was removed in a carcinomatous state some three and a half years ago, had a return of the disease within two years, and took matters into her own hands by employing a quack to treat it with escharotics. I had occasion to examine this lady since, and if she was correct in her conclusion that there was a redevelopment of the cancer, it must be allowed that benefit has resulted from the escharotic treatment. The healing process has proceded so that all the wound is completely cicatrized.

The object lesson afforded by the good result in the case has served to gain another convert to escharotic treatment, in the person of another patient, upon whose breast I had performed a primary operation and a colleague had done a secondary operation for a recurred tumor.

Being impressed with the failure of the knife to avert the carcinomatous growth, the husband of the lady acquiesced in her desire to submit to the escharotic treatment on the occasion of the reproduction of the tumor a second time. In my operation the mammary gland was removed, but finding no involvement of the axillary glands, this region was left untouched. When the second operation was determined upon, in my absence from the city, the colleague upon whom it devolved found an enlarged lymphatic gland near the anterior axillary fold, which was removed by the extension of his incision from the site of the tumor, so as to include this gland.

This complete operation did not secure any better result than my incomplete operation had done, and within a very few months I was called again to verify, not alone the return of the tumor, but also the development of the gland. My opinion was requested as to these growths, which were pronounced to be indications of an unmistakable kind, that the carcinomatous disease had not been eradicated. It was also stated that, in view of the past failures with the knife, little was to be expected from the third cutting operation for the extirpation of the reproduced tumor and gland, and the husband was left to his own choice in selecting the treatment of escharotics on this occasion.

The great suffering inflicted upon the patient by the employment of escharotics in the treatment of malignant growths is an objection of great moment, and yet with the use of morphine the pain is so far mitigated as to become bearable. In a recent treatment of epithelioma of the nose, advanced to the ulceration stage, involving the ala and septum the pain from destructive action of the Vienna paste at the outset and the arsenical paste subsequently, required the free use of hypodermics of morphine and atropia to enable the patient to submit to their applications. He bore the pain in the spirit of martyrdom, as I advised removal with the knife and then to perform a plastic operation immediately to rebuild the nose from the tissues of the cheeks. Upon his urgent request to have the escharotic used, I resorted to this mode of treatment under protest, telling him that it would leave him greatly disfigured to effect a thorough eradication of the cancer. He seems to be now free from disease after the destruction of almost the entire nose.

The relative advantages of the knife and cauteries in the management of carcinoma depend very much upon the progress of the disease. In the incipiency of the local trouble there can be no doubt in regard to the excision being preferable to cauterization, but after full development of a tumor with a tendency to degenera-

tion and breaking down of its structure the resort to escharotics has its advantages in extending to the remote ramifications of the disease. It is a prevalent impression that certain caustic applications attack the diseased structure without affecting the sound tissues and that the so-called roots of the cancer are thus destroyed. There seems to be some just foundation for this belief in regard to application of arsenic, but the destructive effect of caustic potash in the form of Vienna paste extends to every vital structure with which it comes in contact, and the same holds in reference to the plaster of sulphuric acid and charcoal as an escharotic.

The chloride of zinc application is not accompanied with so much pain as the previous named escharotics, and yet does not prove so effective, owing to its less destructive agency.

Quite a number of vegetable products have been likewise employed for the treatment of cancerous affections, but are not so prompt and radical in their effects as the chemical escharotics, and, as a consequence, require a longer time to bring about the disintegration of the morbid growth.

One of the most serious obstacles to the progressive improvement of caustic means applied by so-called doctors is the infatuation that their interests are best served by secrecy as to the remedies used by them. The people who seek their advertised treatment are imposed upon by the air of mystery thrown around their procedures, and if the facts were known, it would appear clearly that there was no virtue in their drugs.

The treatment of carcinomatous tumors of the breast with caustics has been tested fully by Baugard of Belgium. His paste contains chloride of zinc, arsenic, cinnabar and corrosive sublimate. Of one hundred and sixty cases, sixty-two or nearly forty per cent. were free from recurrences three years after treatment.

Bougard's experience leads to the inference that there is something connected with the escharotic application in cases of carcinoma, which is more pervading and far-reaching than simple excision with the knife. As this cauterization does not look to the dissection of the glands from the axilla or clavicular region, it seems that this is not requisite to secure the most favorable results.

Having received a circular letter some two months ago, embodying interrogations upon various points, connected with cancer of the breast, it may not be out of place to incorporate them with my replies.

1. Have you ever seen a breast cancer heal spontaneously? Answer—No.

2. Have you ever lost a case as the direct result of operation, since the advent of antiseptic methods? Answer—Yes.

A single case of encephaloid cancer of the breast of large proportions and necessitating extensive exposure of the thoracic wall, died from shock six hours after complete ablation of the mammary gland.

3. About what is the expectation of life after operation? Answer.—This depends to a large extent upon the period at which an operation is undertaken; those done early recover, and those delayed rarely escape a fatal termination.

4. Have you any case of survival of operation without recurrence longer than three years? Answer.—One case was operated upon nearly five years ago, who has had no return of disease; and is in good health at present. The entire breast was removed without entering the axilla.

5. Have you any cases of survival of operation for three years, and later development of cancer? Answer.—No.

6. About how many cases have you operated upon? Answer.—Ten cases, within the past ten years.

7. Has it been your invariable practice to remove the axillary glands, at the time of operation, or merely in cases when there was evidence of involvement? Answer.—The axilla has not been opened except when there was evident enlargement and induration of the lymphatic glands; and my observation of a departure from this course by others has not proved satisfactory. There is ground for doubt as to the advantage of removing the lymphatic glands even when involved in the disease.

### Tobacco Odors on the Breath.

To remove the smell of tobacco from the mouth or breath, Grahame (*Apotheker-Zeitung*) advises bromo-chloral, a few drops in a glass of water, with which the mouth is to be well rinsed.—*Medical Age.*

# REPORT OF A YEAR'S WORK IN MINOR GYNECOLOGICAL SURGERY IN THE KENSINGTON HOSPITAL FOR WOMEN, PHILADELPHIA.*

CHARLES P. NOBLE, M. D.

I have been led to make this report of my last year's work in minor gynecological surgery by the fact that very little at this time is written about this subject. Whether this is because gynecologists look upon these matters as having been settled, or because their attention is more largely occupied with the problems of abdominal surgery, is an open question. I believe it is the latter, as even cursory reading of such articles as have appeared during the past few years show a great diversity of opinion about the subject under discussion. In my judgment there is no class of work of more importance in the relief of suffering than minor gynecological surgery, and this estimate of its value, under proper conditions, becomes more emphatic with increasing experience. I hope to point out in the comments upon the work reported wherein some have failed to achieve the good results which they had expected, and where others have done positive harm by their work in this field.

There have been one hundred and forty-five operations in minor surgical gynecology done in the hospital during the past year without a death. The operations were divided as follows:

| | |
|---|---|
| Perineorrhaphy and trachelorrhaphy | 24 |
| Dilatation and curetting | 28 |
| Perineorrhaphy | 20 |
| Trachelorrhaphy | 2 |
| Colporrhaphy | 10 |
| General operations | 37 |

It will be seen that in twenty-four cases the cervix and perineum were both sutured, that in twenty cases the perineum alone was sutured, and that in two cases the cervix alone was sutured. These facts are of practical interest, as indicating that, as a rule, when the cervix is torn the perineum is also torn, while the reverse does not hold good. When the disproportion between the head and the cervix is sufficient to cause laceration of the cervix, as a rule, the same accident happens to the perineum; at the same time, the cervix may escape and the perineum be torn, either because of its faulty structure or because of mismanagement of the second stage of labor.

## TRACHELORRHAPHY.

This operation was performed twenty-six times; twice alone, and twenty-four times together with the restoration of the perineum. My estimate of the value of this operation remains unchanged. When the cervix is torn, the womb enlarged, the lips of the cervix everted and eroded, with catarrh of the cervix and of the corpus, and especially when, in adddition, menorrhagia and metrorrhagia are present, there is nothing which will bring about the cure of the patient so rapidly, thoroughly and satisfactorily as Emmet's operation on the cervix. It is true that by prolonged treatment of a general character, and with local treatment to reduce pelvic congestion, very many women with laceration of the cervix can be made reasonably well; but this is accomplished only after tedious effort, and then the condition of the woman is not so good as it would have been had she submitted to operation. When properly done, and with proper indications, the operation is practically without danger, and yields very definite and positive good results. Much harm, however, has been done by operating upon the cervix in improper cases; and also, many cases have not been cured because the work has been poorly done. It is hardly rational to expect to cure a woman having diseased uterine appendages by sewing up her cervix; yet this has been done very many times, with the result that the tubal disease has been made worse, a peritonitis immediately ensuing as a direct consequence of the operation, or resulting later through aggravation of the tubal disease. It should be laid down as a fixed law that the cervix should not be sutured unless the uterine appendages are healthy.

It is my practice invariably to dilate

* Read before the Phila. Co. Med. Soc., October 25, 1893.

and curette the uterus before doing a trachelorrhaphy, and catarrh of the cervix and corpus, existing as a complication, are thus removed. The cavity of the uterus is thoroughly washed out after the curetting, and thus the field of operation is made more thoroughly aseptic, and the possibility of infection by septic discharges from the endometrium greatly lessened. The principles of asepsis are as rigidly maintained as when doing abdominal surgery. The vagina is thoroughly scrubbed with soap and water after the patient is anæsthetized; it is then thoroughly washed with clean water, and later with bichloride of mercury solution. This preparation of the field of operation precedes all operation upon the utero-vaginal canal.

In performing trachelorrhaphy I have the patient in the lithotomy position, and remove the diseased and cicatricial tissue usually with the knife, at times with scissors, being careful to provide for an ample cervical canal; the rent is sutured with full curved needles, using catgut as a suturing material. Of the very many cervix operations that I have done I have yet to see a case in which primary union was not obtained. All suturing materials—silver wire, silkworm-gut, silk and catgut have been employed, and the results obtained have been the same; hence, as it is usually necessary to operate on the perineum at the same sitting, I employ catgut, because this suture material is absorbable, and the stitches do not have to be taken out.

In cases in which the cervix is thoroughly diseased, either by cicatricial tissue, or by cystic degeneration, I believe it is better to do Schröder's operation rather than trachelorrhaphy; in the few cases in which I have done Schröder's operation from this indication, the results have been very satisfactory.

### DILATATION AND CURETTING.

During the past year there have been twenty-eight such operations. This operation is always done for well-marked endometritis, especially if this be accompanied by marked uterine hemorrhage; also for certain cases of dysmenorrhœa. When the pain of menstruation comes on with or after the onset of the flow, and is distinctly intermittent and cramp-like in character, especially if clots are passed from time to time—the passage of the clot being followed by relief of the pain—dilatation and curetting of the uterus has given excellent results. The trouble lies in the selection of the cases. If every woman who suffers pain during menstruation should have her cervix dilated, undoubtedly more harm than good would be done, because in most cases the difficulty is not a narrow cervical canal. It is only those cases where narrowness of the cervical canal is the cause of the trouble that dilatation will be of service. At times, as a result of the narrow cervical canal and the consequent interference of the discharge both of the menstrual and inter-menstrual secretions, endometritis has resulted, for the relief of which curetting as well as dilatation is necessary. If the cases are well studied and the dilator and curette only employed in such cases of dysmenorrhœa as have been referred to, the results obtained will be very satisfactory. The cause of the narrow cervical canal of most importance is a lack of development of the uterus, especially of the *portio vaginalis*.

Much has been written within the last few years of the direful effects of the use of the dilator and curette. The attack upon this operation has been led by Dr. Price, of this city, and all manner of evil consequences has been ascribed to it. Dr. Price has gone so far as to say that the use of these instruments in the hands of others is the reason why he is kept busy doing abdominal surgery. I cannot believe that this is so, because it is so directly at variance with my own experience. I have used the dilator and curette literally hundreds of times, and were they the instruments of evil described by Dr. Price I should have had the evidence of it in my own work; on the contrary, only good has resulted, the exceptions being so rare as to be distinctly remembered, and the reason for such ill results distinctly apparent. They were cases (some three in number) in which, although it was recognized that the uterine appendages were diseased, it seemed best to use the curette to arrest uterine hemorrhage. In these cases the tubal disease was made temporarily worse, yet none of them died, nor were their prospects of cure by means of the radical removal of the tubal disease lessened. It is easy to understand that much harm can be done with the dilator and curette

if they are used in the presence of tubo-ovarian disease, especially if the appendages contain pus. It would be very easy, under these conditions, to cause a leakage of pus into the peritoneal cavity, and a peritonitis. Both on this account and because it is irrational to expect to cure such a patient by the use of the dilator and curette, in my judgment, under these conditions, these instruments should not be employed, or only under exceptional circumstances. I believe that the ill consequences attributed to dilatation and curetting have been due to this error in the selection of cases, and that the many cases referred to by Dr. Price, in which he believes that serious disease of the appendages was caused by the use of the dilator and curette, that in reality the uterine appendages were diseased before dilatation and curetting were done, and that this disease had simply pursued the usual course, or perhaps had been aggravated by the treatment adopted. Under proper aseptic methods, dilatation and curetting of the uterus, when the tubes and ovaries are healthy, is a harmless procedure on the one hand, and upon the other hand it is one capable of doing great good in the special class of cases of dysmenorrhœa referred to, and whenever endometritis exists.

My opinion concerning the safety with which the uterus can be dilated and curetted under the conditions laid down has been strengthened by the work of certain New York surgeons, especially Dr. Polk, who has employed dilatation and curetting of the uterus in large series of cases in which the appendages were diseased, and this he claims not only without harm, but with benefit, especially in cases of catarrhal salpingitis. While his practice and experience have not induced me to extend the indications for this operation in my work, yet they bear heavily against the argument that dilatation and curetting is so potent for evil.

PERINEORRHAPHY.

There have been forty-four cases of perineorrhaphy during the year. The method of Emmet has been followed, and the results obtained have been most gratifying. Primary union was obtained in forty-two patients; in two cases infection and suppuration prevented union. Emmet's operation upon the perineum is a most admirable addition to surgery, and by it results are obtained, where the injury is extensive, involving the levator ani muscles, which cannot be obtained by the methods usually employed. I believe that this operation is the chief work that Dr. Emmet has given to the profession, and of itself would be enough to give him lasting fame. I was prepared to accept Emmet's operation by my training in an obstetrical hospital, where careful study of many lacerations of the perineum during labor demonstrated that these laceration are never median, except at the posterior commissure of the vulva. At the plane of the hymen, which corresponds to the deep perineal fascia, the laceration always becomes lateral; it extends up one or both sulci of the vagina, and, aside from the skin, mucous membrane and connective tissues, involves a laceration of the perineal fasciæ, transversus perinei and levator ani muscles. A rational operation should have for its object the bringing together of these sundered structures. The denudation must involve the torn commissure of the vulva and the torn sulci of the vagina. The credit of recognizing this is due to Emmet.

The originators of the old median operations, the best of which is Hegar's, did not recognize these facts, and indeed they based their operations upon the old erroneous teaching concerning the perineal body. The aim of all such operations is to build a buttress of tissue between the vagina and rectum, with the idea that it, because of its wedged shape, will act as a support to the pelvic organs. It was not recognized that the support of the pelvic organs depends upon the integrity of the levator ani muscles and the pelvic fasciæ, and that the object of the operation, when these structures are torn, is to restore them as nearly as possible to their original condition.

In doing the operation I have usually denuded higher up the sulci than does Dr. Emmet, and have taken care to secure a small introitus by carefully denuding and suturing the torn posterior commissure of the vulva. Catgut sutures have been employed high up in the sulci, and silk sutures through the torn ends of the levator muscles and for the remaining sutures. The results from this operation are more certain and satisfactory than

from any other in gynecology. When a woman has suffered from severe injury of the levator ani muscles and pelvic fasciæ, she has all the symptoms of a hernia; she feels as though the pelvic contents were dropping out. To restore the pelvic floor in such a case to its normal condition is to make the woman a new creature.

PROCIDENTIA.

There have been ten operations for procidentia, either partial or complete. The method employed in operating for procidentia, excepting one case, was to do first a high amputation of the cervix. The vagina is cut loose from the cervix, the bladder pushed off in front and the peritoneum behind. The lateral attachments of the cervix are ligated and cut away, and then about one inch of the cervix is amputated; the cut vagina is then stitched to the cervix, the mucous membrane of the vagina to the cervical endometrium, in this way covering the stump of the cervix with mucous membrane. Next anterior colporrhaphy is done. Stoltz's method is used when there is much cystocele, otherwise the ordinary oval denudation. And finally, Emmet's perineorrhaphy is done, the denudation being made as extensive as possible; the object being not to restore the parts strictly to their normal condition, but in addition to this to make the vagina and the introitus as small as possible.

I have used this method of operating now for four years, and my experience is that by it fully ninety-five per cent. of cases of procidentia can be permanently cured. I know of only one case in which it was a complete failure.

Procidentia of the uterus, almost without exception, is due to laceration of the pelvic floor, involving the pelvic fasciæ and the levator ani muscles. As a consequence of this injury the pelvic viscera are not properly supported, and rectocele, cystocele and prolapse of the uterus ensue. This result is brought about more rapidly in women obliged to do laborious work, and is favored also if for any reason the womb is enlarged and retroverted. The exceptions to this rule are extremely rare; I have seen but one myself. This was a case of complete procidentia in a nulliparous woman. She had been obliged to do laborious work involving much lifting; her womb doubtless had become retroverted, and, having naturally lax tissues, the intra-abdominal pressure had forced down the uterus, distended the perineum, and turned the vagina inside out. As illustrating the nature of the case, she was completely cured by the use of tampons and the pessary. It is important to insist upon the curability of procidentia, because the reverse of this teaching has been advanced of late, and it has been urged as a reason for performing hysterectomy for procidentia. In my judgment this procedure is illogical unless the uterus contains a tumor or is of great size. It might be advisable also in those rare cases of long standing procidentia and rectocele, in which the tissues of the pelvic floor have become atrophied from long continued over-distension, which prevents the restoration of the pelvic floor.

The philosophy of the method of operating for procidentia which has been advocated is clear. By amputating the cervix the size and weight of the uterus is decreased; and a further gain is made by the removal of the cervix, as this, when present favors the prolapse of the uterus by acting as a guide down the vaginal canal, being deflected forward as the uterus descends by the posterior wall of the vagina. By means of the anterior colporrhaphy the slack of the bladder is taken up and the anterior vaginal wall becomes a straight line from the pubic arch to the cervix, as it should be. And finally, the operation upon the perineum restores the integrity of the pelvic floor and insures a permanent cure by affording an adequate support to the pelvic viscera.

GENERAL OPERATIONS.

The thirty-seven general operations consist of the removal of polypi, the excision of papillomata about the genitalia, scraping operations for cancer in cases in which the disease was too advanced for a radical operation, the closure of two vesico-vaginal fistulæ, the excision of the mammary gland, etc. As I have no suggestions to offer in the performance of these operations that differ from the accepted teachings, it is unnecessary to discuss this subject.

GENERAL CONSIDERATIONS.

Success in minor surgical gynecology, and especially in plastic work, depends up-

on a thorough gynecological training, and especially upon a knowledge of the anatomical side of the pathological conditions involved, upon the faithful employment of aseptic methods, and especially upon careful work in suturing. Thorough preparation of the field of operation by careful scrubbing with soap and water, the plentiful douching with plain boiled water, followed by bichloride of mercury solution, is just as important in this class of work as in any other, With an aseptic field, with aseptic sutures and instruments, and with aseptic hands, primary union should be almost invariably obtained. In my entire experience in operating upon the utero-vaginal canal I can recall only three cases in which primary union was not obtained, and in only one or two more did infection along the sutures result in the formation of pus; and in these cases primary union was not prevented.

The suturing material employed in this class of work is somewhat a matter of indifference, as a good operator can obtain perfect results with any of the recognized suture materials, provided it is aseptic. I have long given up silver wire because it is troublesome to use and possesses no real advantage for this work. Silkworm-gut is a most excellent material, but is stiff, and therefore the stitches are more painful to remove than are silk stitches; for this reason, unless there is good reason to fear infection, I do not employ it. In complete lacerations of the perineum into the bowel it should be used in preference to silk. Properly prepared catgut has given me complete satisfaction. This I think is because it has been used only when no tension is to be feared. In the cervix it answers perfectly; also for the upper sutures in the perineum. Whereever tension is expected silk has been employed, and answers every expectation. I should hesitate to use catgut for the lower important sutures in doing perineorrphapy, because straining at stool, or coughing on the third or four day, when the catgut sutures have become weakened, might cause the wound to burst open. There is little difficulty in removing four or five silk sutures from each sulcus of the vagina; and the advantage that the silk will sustain the straining at stool or coughing more than compensates for the trifling discomfort of removing these sutures.

In placing sutures, the operator should always bear in mind what he wishes to accomplish with the suture; if he desires to make surfaces unite the one to the other, the suture must be placed so that when tied it forms a circle or nearly a circle. In this way the surfaces are brought together smoothly, and are held together. Superficial sutures placed parallel to the surfaces which it is desired to unite, act as puckering strings, throw these surfaces into folds, and defeat the object aimed at. This apparently simple matter makes all the difference between success and failure in plastic work.

---

### Parasites in India.

The *British Medical Journal*, 1893, p. 807–808, in reviewing Dr. Jobson's work in connection with Beri-beri, gives the following interesting statistics of the presence of parasites in 1,249 natives of India.

| PARASITES | Cases | Per Cent. |
|---|---|---|
| Anchylostoma duodenale | 944 | 75.58 |
| Ascaris lumbricoides | 131 | 10.49 |
| Oxyuris vermicularis | 192 | 15.36 |
| Flukes Distoma crassum | | |
| Amphistoma hominis | 13 | 1.04 |
| Trichocephalus dispar | 55 | 4.04 |
| Insect larvæ | 6 | 0.48 |
| Tape worms | 18 | 1.44 |
| Free from parasites | 204 | 16.3 |

---

### The Clinical Regions of the Abdomen.

In *The Jour. of Anat. and Phys.*, Professor D. J. Cunningham contributes an interesting article on "Delimitation of the Regions of the Abdomen." He recommends that the upper horizontal line should be drawn at the lowest part of the tenth costal cartilages, which is the lowest part of the chest wall as seen from the front. The lower horizontal line is one of more difficulty. Dr. Cunningham suggests one uniting the prominent tubercles on the iliac crests, about two inches behind the anterior superior iliac spines. This line is distinctly below the unbilicus, and puts almost the whole of the iliac fossa in the iliac region. The vertical lines are drawn, one on either side, through the middle of Poupart's ligament.—*Edinburgh Med. Jour.*

# BIOGRAPHICAL SKETCH OF THE LATE ISAAC N. KERLIN, M. D.

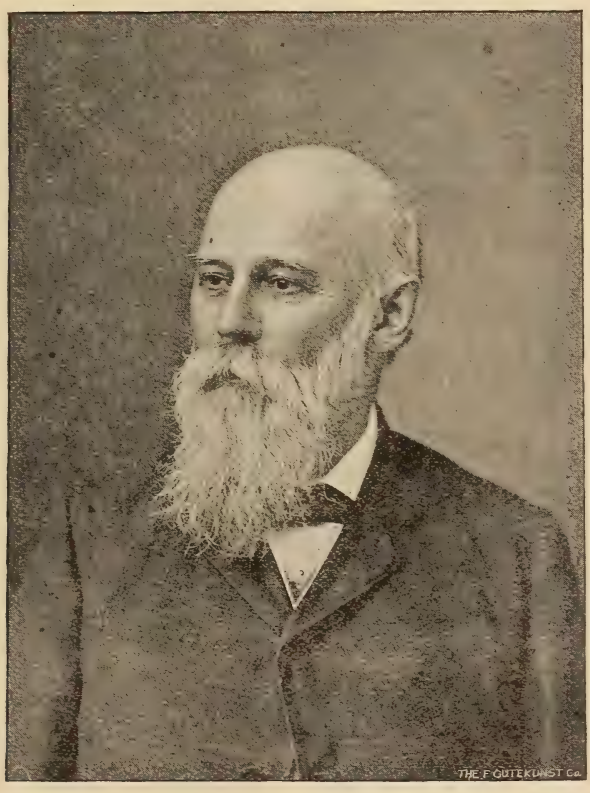
LAURENCE TURNBULL, M. D., P. H. G., PHILADELPHIA.

Physicians may be divided into four great classes.

In the first class the individual enters and makes the profession like any other occupation, a simple means of livelihood, acquiring sufficient medical knowledge by the smallest amount of study and preparation. His chief object is to obtain his degree. He enters upon the practice of this noble profession without hesitation or fear of its grave responsibilities. His main object in life is to acquire patients who can pay; with this idea he attends every call promptly. He takes special trouble by inquiry in regard to the amount the patient earns, his salary or income, and charges accordingly. If not paid promptly he soon ceases his visits, having no compassion for the poor, or, God Almighty's patients.'

The second class is the young physician who may have talents and ability with too high an estimate of himself, lacking energy and good common sense. He devotes too much time to chemical or other scientific experiments; and when called at night, in a storm, or when engaged in some interesting occupation, refuses, or sends to a more willing neighbor. The same individual wonders why he has not a lucrative practice or perhaps sneers at, and ignores his more willing and successful rival.

The third class is the literary, college or



ISAAC N. KERLIN, M. D.

high school graduate, with a knowledge of the dead languages, Latin and Greek to assist him in the derivation of his medical medical words, thoroughly versed in orthography and *belles-lettres* able to write well and spell correctly. Having also certain most useful accomplishments, such as the German and French languages, with practical chemistry and physics, above all a mechanical turn for the handling and use of instruments of precision, giving him a great facility for all the operations on the human body. He fortunately has the opportunity of a hospital appointment, or work in a dispensary district, attending the poor for a nominal sum, acquiring a reputation among them, and when able, they are glad and willing to pay. He adapts himself to their needs, giving them words of sympathy and kindness. By taking both time and trouble studying, up each case, he is successful in curing his patients and he receives his reward in a large and lucrative practice, with their heart-felt gratitude.

A fourth class, enters the profession with a high and lofty object, making every effort to attain the highest average in the examination, graduating not in haste but filling up the full number of years of study. Then with an anxious and great desire to further improve theoretical knowledge, enters a hospital to see every variety of human suffering and diseases treated by the highest talent.

Thus did Isaac Kerlin, first in the Wills Hospital and then as assistant to Dr. Parrish, fit himself as an expert in the almost incurable forms of disease he had to treat. Ultimately becoming the successor of Dr. Parrish as physician and superintendent, he gave personal attention to minutest details in every part of the institution.

Such was our friend, tender as a woman to the poor creatures under his care, acting the part of father, guardian, and true friend. Yet in everything that required tact and decision, he was equally up to the mark. It was his to do and dare what was right and true.

Let us view the beginning of his work at the Institution. A very modest building with poor accommodations and now, see the noble structure erected with every appliance for the instruction of the almost idiotic child, with appliances to bring their bent and crooked bodies back to their proper form, as suitable tabernacles for the bright minds and souls, fitted for use on earth and a brighter future in heaven !

With the Doctor every one was taught both by precept and example how to reach that better home where he has gone before.

---

Isaac N. Kerlin, M. D., was born in Burlington, N. J., May 27, 1834. His parents were Joseph Kerlin, grandson of one of the Penn settlers on the banks of the Delaware, and Sarah Ann Ware, daughter of John T. Ware and granddaughter of John Ware, both prominent shipbuilders, the former connected with the Philadelphia Navy Yard and an inventor of special methods for lighting the interior of vessels. Educated in the public schools and the John Collins Academy at Burlington, N. J., under the preceptorship of the late Dr. Joseph Parrish, he entered the University of Pennsylvania and graduated as doctor of medicine in 1856.

He was appointed resident physician at Wills Hospital in 1875, from whence he was called to the assistant superintendency of the Pennsylvania Training School for Feeble-minded Children, then in its infancy, in October, 1858. He enlisted in the emergency call in 1862, when the advance of Lee's army threatened Philadelphia ; but was called from the ranks by the late State Surgeon-General Henry H. Smith, and placed by him in charge of the night work of the improvised hospital at the Hagerstown Court House, where on the gloomy nights of September 17–21, he gave efficient and faithful service. Three weeks after he was entrusted by Medical Director A. K. Smith, of the United States Army, with the removal of the wounded who were able to be transported to Chambersburg, Harrisburg and Philadelphia. From this service he was called by the United States Sanitary Commission and sent to one of its outposts in Suffolk, Va. Attention was so called to the nature of his work, and especially to his sympathy with the black refugees from the Chowan, that he was recalled to Washington and identified with an inter-

esting epoch in the history of the war which is not widely known. President Lincoln, in December, 1862, was harassed and wavering as to what should be done with the great mass of negroes escaping from slavery, and who were then in wretched condition in camps in and about Washington. He conceived a colonization plan ; the Island of Vache had been leased or acquired to carry out his project, and vessels lay in the Potomac loaded with the blacks and provision for establishing villages when they should have arrived at their destination. The late Henry W. Bellows, president of the United States Sanitary Commission, and Dr. Samual George Howe nominated Dr. Kerlin to the President for the important service of director of the colony of Vache. Pending his arrangements to take charge of the emigrants, small-pox broke out in the fleet, heavy storms arose and the scheme was reluctantly abandoned by the President, to be followed in the spring by the Contraband act, which forever settled the mind of the President as to what to do, or what not to do, with the blacks. After this, Dr. Kerlin was moved by the principal officers of the Commission to the charge of the field work of the Sanitary Commission of the Army of the Potomac, then badly needing reorganizing, and here he remained until after the battle of Chancellorsville in May, 1863, winning for himself the approval of the Commission by his organizing ability and indomitable energy. Later he was urgently recalled to his old post at the Pennsylvania Training School for Feeble-minded Children, and succeeded Dr. Parrish as superintendent in November, 1863. His name and life are inseparably connected with that institution and with the uplifting of this unfortunate class; but he kept himself in intimate touch with the medical profession of the state and country, contributing to the journals, numerous articles bearing on the subject of idiocy, and was a member of County and State medical associations. In connection with the care and training of the feeble-minded he was the author of two small volumes, "The Mind Unveiled," 1859, and "The Manual of Elwyn," 1891. In July, 1876, he invited to Elwyn the superintendents of the then existing institutions for the feeble-minded and organized a national association, the proceedings of which for the first decennial period were edited and published by him in a volume of four hundred and fifty pages.

In 1889, Dr. Kerlin, in company with his wife, made a protracted foreign visit and were the guests of Dr. Hack Tuke, Jonathan Hutchinson, the late Joseph Beck and of almost all the prominent institutions for the feeble-minded in Great Britain, Norway and Denmark. His wife, Harriet C. Dix Kerlin, closely identified with and honoring his life work, died in December, 1892, leaving four sons—John Ware Sharpless, Isaac Newton, Jr., Ward Dix and Thaddeus Leavitt.

The funeral of Dr. Kerlin, who died Wednesday night, October 25th, was held on October 28th, at his residence at Elwyn, Delaware county. There was a large attendance of friends and officials and attachés of the school over which the doctor had presided for thirty years, with several of his most intimate medical friends. The interment took place on the grounds of the institution. He was placed in a vault built to contain his beloved wife's remains. The Board of Directors held a meeting previous to the funeral and adopted appropriate resolutions of regret and of condolence with the bereaved family.

Dr. Kerlin had not only devoted the best years of his life to this school and won for it the highest rank among institutions of the kind, but he framed the original draft and secured the passage of a bill through the Legislature for a similar institution in the western part of the state. The site for the new school has been selected at Polk, Venango county, Pa.

Mr. Gutekunst has furnished a most admirable and speaking likeness of the Doctor, with his dome-like forehead, his well-shaped nose, and above all the peculiarly happy twinkle of the eye with which he greeted his friends.

God give us, like him,
Strong minds, great hearts, true faith and ready hands;
Men whom the lust of office does not kill;
Men whom the spoils of office cannot buy;
Men who possess opinions and a will;
Men who have honor; men who will not lie.*

ISSUED EVERY SATURDAY

ADDRESS

Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

PHILADELPHIA.

**TERMS**:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

**REMITTANCES** should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

**NOTICE TO CONTRIBUTORS**:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, NOVEMBER 25, 1893.

## EDITORIAL.

### RESPONSIBLE CRANKS.

From the time that irresponsibility was first urged in extenuation of criminal acts, insanity has proved a city of refuge to wrong-doers. Imagination could not devise a weapon of defense more elastic, more elusive nor more efficient. An astute lawyer can make the term 'insanity' cover almost anything from the 'incapability' of the man of property—which is suspected for the first time when some disappointed heir solicits a microscopical examination by the probate court, through the 'temporary aberrations of mind'—which charitably explain the suicide of the debauchee, the unfortunate lapse of the trusted employee, or, in fact, any overt act of moral turpitude that is found out, to the atrocities committed by the violent maniac.

This plea more than any other, perhaps, has righteously served to protect unfortunates from 'man's inhumanity to man,' and likewise, more than any other, it has unrighteously served to elevate crime to a speculation with the chances in favor of the criminal. So intangible is it that the testimony of medical science is practically valueless in the courts and the 'medical expert' has become a by-word.

The daily papers report that a thorough medical examination shows the assassin of the late mayor of Chicago responsible for his acts. This is as it should be so far as our information goes and relying on general principles.

There is one phase of the question which it is desirable to take into consideration. An author, writing for the *Open Court*, presents the very sound view that the theory of political assassination is a justification of private murder. The recent expression, called out by the murder of Mayor Harrison, is but the echo of his words written when Alexander II. was killed by the explosion of a Nihilist's bomb. He then said: 'Once admit the right of assassination as a remedy for political evils, and there will always be somebody under sentence of death, a mark for the private executioner. It is the menace of death to every man above the grade of a tramp."

This is a logical and an absolute statement. Deductively, therefore, they who advocate the murder of a sovereign, ruler, or Governor are promoters of assassination, which is very little different from being accomplices to murders committed in pursuance of those theories of political assassination. The man who incites to crime is as guilty as the man who commits the crime. That has always been held in the case of hired assassination. The man who gives another a certain sum to do a murder, or promises him a material reward on the execution of the deed, is a principal to the murder. Now, it does not make much difference what the nature of the reward may be, whether it be money, food, or the assurance of a bettered condition. The incentives to murder may be as different as are the varieties of murderous actions.

If, therefore, General Trumbull be right in his proposition, the orator who tells a crowd that peace, happiness, independence or prosperity will follow the killing of the rulers or capitalists is indisputably an accomplice with the man who rushes off and kills a ruler or a capitalist. Incitement to murder is no less heinous than the procuring of murder to be done by the payment of reward to the murderer, and the sophistry that condemns the actual commission of a crime and pleads for the immunity of the instigators, the suggestors of the crime, will hardly persuade the American people to destroy the tool and do no harm to the hand that drove it home.

If men who, acting under the influence of incendiary speeches of specious orators, shoot down or cut down some public character are to be exempted from punishment on the plea that they are "cranks" or lunatics, there can be no restraint put upon murder. To use the very words of General Trumbull, that would "threaten every man in America who can wear a decent coat."

There is a responsible insanity. If we hang some of the so-called "cranks" whose "insanity" takes the form of killing the men who displease them we will have fewer assassinations. The example of the gallows uncompromisingly employed is a superb check upon the exhibition of homicidal crankiness. Cranks can reason very well in the eye of the gallows.

## THE FOOD EXPOSITION.

The Retail Grocers' Association of Philadelphia have for a number of years past held annual meetings of the 'Pure Food Exposition.' The association is formed for the protection of dealer and consumer alike from adulterated food-stuffs and injurious compounds; for the encouragement of the manufacture of pure products, and for the introduction to the public of novel and meritorious food preparations. The annual exhibition has been remarkably popular, especially among intelligent ladies who have at heart the interests of the healthy home and family.

While the exposition is of immediate value to the exhibitors, being a most successful mode of advertising, it has a much greater, though less definite, value to the public at large in that it is an educational factor of no mean importance. The exposition will be of benefit to medical men and it will repay inspection and study. Not only are the exhibits open to free inspection, but information as to composition and methods of manufacturing is freely given. Instructions are furnished as to mode of preparation of various food articles, and liberal samples are allowed

for experiment and trial. The whole exposition is a popular object-lesson of the scientific production and preparation of food materials.

A very valuable and perhaps the most popular feature of the annual exhibition is a course of lectures and demonstrations on the preparation of food, given by Mrs. S. T. Rorer, a teacher of national reputation. This lady whose intellectual powers and tireless energies would make her pre-eminent in any calling, has devoted herself to the scientific investigation of foodstuffs and the best methods of preparing them, and to teaching the practical application of the results of her study. Having more than ordinary information as to the physiological and chemical processes involved, she has a right to speak as one having authority, and, always ready with a reason for the faith that is within her, should be heard with attention and consideration.

One lecture in the course for the special benefit of physicians, is given to the preparation of food for the sick, and the physician who is fortunate enough to hear the lecture will find he has gained more of practical benefit from this clinical demonstration than he could glean from physiologies and chemistries innumerable.

# BACTERIOLOGICAL NOTES.

## RESEARCHES ON CHOLERA AND VIBRIOES.

Metschnikoff (*Annales d L'Institute Pasteur*, 1893, vii, p. 562), describes the pathogenic effect of several vebrios or comma-shaped spirilla as revealed by a series of inoculation experiments. He has also studied their effect in passing through the human body, more especially the effect which such a condition would exert upon the virulence of the growth. The results of bacteriological investigations during the past few years has resulted in the discovery of a large number of *spirilla* which resemble very closely the germs of Asiatic Cholera described by Koch in 1884 in the excreta of cholera patients. The more important of their forms Metschnikoff has tested so far as their pathogenesis goes. These conclusions are of considerable interest. He confirms Koch's results in that he believes the comma bacillus of Koch is the real cause of Asiatic cholera, notwithstanding its clear resemblance to other spirilla, especially the vibrio metschnikovii. Although he considers this germ to be the cause of the disease, it is an undoubted fact that immense quantities of cholera bacteria can be taken into the intestine without causing cholera. In order to acquire the disease he thinks that the body must be in a state of peculiar susceptibility, the exact nature of which he does not attempt to explain. It is not a question of a predisposition to indigestion, but something quite distinct. The conditions under which cholera vibrio are found in man are very complicated. These microbes, as well as the product of their growth, enter into multiple relations with the digestive juices and the cells of the organism (host.) On the other hand, these bacteria and toxines come in contact with other micro-organisms in the digestive tract and undergo the action of their various products. Judging from what has been done it would seem that the method of vaccination through the digestive tract is much more efficacious than by the hypodermic method. It appears also that the other vibrioes analogous to the cholera vibrio may be pathogenic to man. It may be considered as true that the natural cure of cholera is accomplished without any preventive power being set up in the blood. Finally, he believes that cholera runs its natural course without the production of a preventive property or substances in the blood. The differentiation of certain of the intestinal spirilla from the cholera vibrio is found to be exceedingly difficult.

## PHYSIOLOGICAL ACTION OF THE ALBUMOSES FOUND IN THE TISSUES IN DIPHTHERIA.

Martin has contributed some interesting facts to our knowledge of the action of diphtheria bacteria. The work deals with the albumoses found in tissues of diphtheria patients and in cultures of the specific bacteria and their effect upon animals. His work is published in full in its *Report of the Medical Officer of the Local Government Board* 1891–1892 from which the following conclusions are taken.

1. "The bacillus diphtheria forms in diphtheria membrane and in culture media, proteid products of the same chemical nature as those found in the bodies of patients dead of diphtheria, viz., albumoses and an organic acid.

2. The albumoses formed by the bacillus diphtheria in artificial cultivation, have in single and multiple doses the same physiological action as those found in the human body after death by diphtheria. This action is the production of fever, of diarrhœa, of loss of body weight, and of a progressive paresis of the muscles, resulting from a degeneration of the peripheral nerves.

3. The bacillus diphtheria is, therefore, the primary infective agent in diphtheria.

4. The diphtheria bacillus liberates in the membrane a ferment which when absorbed digests the proteids of the body, forming albumoses and an organic acid.

5. These digested products, which are the agents in producing death cause the fever and the depression, and as well the paralysis which follows diphtheria."

A further interesting point to which Dr. Martin calls attention is, quoting his own words, "It is clear from the cases of diphtheria which have been described that the diphtheria products found in the body do not all come direct from the membrane." This conclusion is reached from the fact that in certain cases where there was very little membrane there was a larger amount of diphtheria products in the body. He also believes that there is something more than absorption taking place from the fact that the spleen contains a large quantity of the albumoses and the organic acid, while their specific physiological action shows that they are foreign to the normal body. He believes it more probable that the ferment absorbed from the membrane digests the more or less stagnating proteids in the spleen.

# TRANSLATIONS.

## THERAPEUTIC HINTS FROM FOREIGN JOURNALS.

IN CHARGE OF THE TRANSLATOR, F. H. PRITCHARD, M. D.

### MERCURIAL TREATMENT OF GLANDERS IN THE HUMAN SUBJECT.

Dr. L. K. Gralewski (*Sel-I-Kwai-Medical Journal,* No. 9, 1893) details a couple of very instructive cases of human glanders treated by inunctions of mercury. A gentleman, of forty years, was attacked with acute glanders, in a very severe form and succumbed on the twenty-seventh day, notwithstanding treatment by antipyretics, tepid baths, painting the ulcers with carbolic acid and the internal administration of the iodide of potash. A relative of his, an old gentleman of seventy, yet strong and in good health, contracted the disease and presented itching pink papules on the hands, back, neck and feet. When seen on the seventh day of the symptoms he complained of general prostration, headache, and fever of 39. 8° C. There were besides a crateriform ulcer, with uneven and undermined edges and a congested and elevated encircling zone, and abscess of the size of a walnut on the back of the neck. This was evacuated and, together with the ulcer, painted with carbolic acid and mercurial ointment, in doses of four grams (one drachm) was prescribed epidermically.

In about five days the nodules ceased appearing, the old papules were transformed into small pustules, while others—those freely painted with carbolic acid—sloughed away in ten to twelve days, leaving a delicate pink skin. The course of the disease was exceedingly obstinate and protracted, a complete recovery ensuing about the seventieth day. The total quantity of salve used was about two hundred grams (six ounces and a half). In spite of this energetic use of the drug not the slightest sign of mercurialization was remarked, though a gargle of the chlorate of potash was employed as a precautionary measure. The other case was that of a peasant woman of thirty-five, the servant of the family, who washed the linen of the deceased. She had a fissure in the skin of the dorsum of the right hand between the thumb and forefinger which, on the third day after her last washing, was transformed into a rapidly increasing abscess which in four days attained the size of a hen's egg, while there supervened headache, pain about the hand, and high fever. The pus cavity was opened and washed out antiseptically and mercurial inunctions were ordered. Rapid improvement followed, the patient making a perfect recovery, in seventeen days. Only forty-eight grams (an ounce and a half), of the salve were employed in this latter case. The author adds that while both the adults who nursed the patient contracted the disease, his three children, aged from four to ten years, who were all the time in the closest possible contact with him—laid in bed with him, kissed him, etc. —did not contract the affection. Children hence seem not to be very susceptible to the virus of glanders.

### DYSMENORRHŒA.

Dr. V. Cocq (*La Semaine Medicale*, No. 59, 1893) recommends the following formula in dysmenorrhœa:

℞ Fluid Extr. Viburnun Prunifolium,
Fluid Extr. Jamaica Dogwood, ana 2 gms. (gtts xxx.)
Elixir of Garus,..... 20 gms (3v).
Simple Syrup..... 30 gms (3j).
Water..... 140 gms (3 ivss).

A Dessert spoonful every two hours.

### SALICYLIC ACID AS A TAPE-WORM REMEDY.

Dr. Ozegovski (*Medicinische Neuigkeiten*, No. 36, 1893) speaks highly of salicylic acid as an expeller of tape-worms. He administers it as follows. The patient eats no dinner nor supper, and in the evening takes an ounce of castor oil (thirty grams). The next morning another dose of castor oil, of fifteen grams (½ ounce) is prescribed and from eight o'clock on, a gram (fifteen grains) of salicylic acid, every hour until four doses have been taken. If the worm is not expelled after the fourth dose, another dose of half an ounce of oil may be ordered.

### CHLORATE OF SODA IN CANCER OF THE STOMACH.

Dr. Brissaud (*Weiner Medizinische Presse*, No, 42. 1893) knowing the favorable influence of the chlorate of potash in epitheliomata of the mouth and certain forms of cancroids of the face, was led to try chlorate of soda in carcinoma of the stomach. The soda salt has the advantage of being more soluable and less poisonous than the potash salt. By its employment, in doses of eight to sixteen grams, per diem (two to four drachms) he has obtained undoubted improvement in pronounced cases of carcinoma of the stomach with distinct tumor. Under the influence of this treatment, in five cases where the diagnosis was unquestioned, the vomiting of blood ceased, the appetite returned, the cachexia disappeared and in three cases where there was a distinct tumor in the epigastrium, it disappeared completely. He left all cases where there was any doubt entirely out of his report. The epithelial forms are especially those which are favorably influenced, but the interstitial carcinomata were unimproved. On the contrary, there are cases where no such result is to be expected on account of already existing metastases, or grave complications. Other physicians—Hanot, Legendre, have obtained astonishing results with the chlorate of soda, in carcinoma of the stomach. Lepine, of Lyons, has used the chlorate of potash with good results in epitheliomata. He advises not only the use of the remedy but in large doses.

### CRYSTALLINE A SUBSTITUTE FOR COLLODION.

Dr. L. Phillips (*La Semaine Medicale*, No. 59, 1893) presents this substance, a solution of pyroxyline or gun-cotton in methyl alcohol, as a substitute for collodion. It is analogous to collodion but it

evaporates less rapidly and forms upon the skin a translucid, durable and imperceptible film upon the face instead of the opaque and friable pellicle of collodion. Hence it is of especial value in the application of remedies to the face and its slow evaporation enables it to be handled more easily. Its sole inconvenience is its penetrating odor. An elastic crystalline may be prepared as follows :

℞ Crystalline ..... 20 gms. (ʒ v).
Castor oil ..... 5 gms. (ʒjv).
Canada Balsam ..... 10 gms. (ʒijss).

An excellent white varnish may be prepared as follows :

℞ Crystalline ..... 30 gms. (ʒ j).
Castor Oil ..... 4 gms. (ʒj).
Oxide of Zinc ..... 8 gms. (ʒij).

Crystalline easily dissolves salicylic acid, pyrogallic acids, chrysarobine, sublimate and many other remedies. He has found it of service as a vehicle in various forms of tenia tonsurans, warts, eczema marginatum, lupus erythematosus, syphilides, acne and keratoses. The complete transparency of the pellicle permits one to follow the results of treatment more closely. In confluent acne of the face he has gotten excellent results by the following treatment : the affected part is sponged with a solution of lysol which is allowed to act for a few minutes, then the skin is dried by means of blotting paper and is then covered with a fine film of crystalline. This is left in place for eight days when, on removal, a second application of lysol and crystalline will suffice to effect a cure.

---

PHENOSALYL AN INNOCUOUS ANTISEPTIC.

Dr. de Christmas (*Le Progrès Mèdicale*, No. 38, 1893) presents the following compound antiseptic which is nearly as powerful as sublimate and possesses none of its inconveniences.

℞ Carbolic Acid ..... 9 gms. (ʒijss).
Salicylic Acid ..... 1 gm. (grs. xv).
Lactic Acid ..... 2 gms. (gtts. xxx).
Menthol ..... 10 cgms. (grs. jss).

This mixture which he calls phenosalyl, is but very slightly toxic, being but two times less active than sublimate is only necessary to use it in very dilute solutions, from 5–7.5 : 1000. In the proportion of 20 : 1000 it will sterilize completely tuberculous sputa—one of sputa to five of solution—after fifteen minutes. It is prepared by heating the three acids to liquifaction and then adding the menthol. It is very soluble in glycerine and in water in proportion of four parts per hundred.

DIPHTHERIA.

Dr. Trouillet (*Il Racooglitore Medico*, No. 10, 1893) recommends the use of Gaucher's collutory, which composition is as follows:

℞ Tartaric Acid ..... 1 gm. (grs. xv).
Carbolic Acid ..... 50 gms. (ʒjss).
Camphor ..... 20 gms. (ʒv).
Alcohol ..... 10 gms. (ʒijss).
Castor oil ..... 15 gms. (ʒiv).

Apply locally with a camel's hair brush, several times a day. With this local application the membranes disintegrate and are easily removed. It does not destroy the epithelium nor give rise to secondary infection.

---

HYPODERMIC INJECTION OF MERCURIAL OIL IN CEREBRAL SYPHILIS.

Dr. J. Sacaze (*La Semaine Medicalè*, No. 59, 1893) observed three cases of cerebral syphilis which he treated successfully by hypodermic injection of mercurial oil. The first was a woman of thirty-five, who for about five months had had a very severe headache with nocturnal exacerbations which had resisted the ordinary measures. As certain symptoms were remarked which pointed to syphilis of very recent date—symmetric copper-colored patches on the internal surface of the knees, falling out of the hair and enlargement of the inguinal glands—it was diagnosticated as of syphilitic origin. Inunctions of mercurial salve and two grams (gr. xxx), of the iodide of potash, per diem, after five days' use being followed by no results, a hypodermic of gray oil, not an intramuscular injection, was made, the oil being prepared according to the following formula:

℞ Metallic mercury ..... 20 gms. (ʒv).
Lanoline ..... 5 gms. (ʒjss).
Liquid vaseline ..... 35 gms. (ʒj. 1-4)

Each cubic centimetre, (fifteen grains,) contains fifty centigrams (eight grains) of mercury. From five to seven cgms. (three-fourths to one grain) of mercury were injected at a time. The headache diminished in intensity from the moment the injection was made and it disappeared completely by the fifth day. The first was made the 10th of March, the other three, the 24th and 31st of March, and then one on the 7th of April. The 27th of April, the headache reappearing, another injection was given and it disappeared the next day. Since then several

injections, at regular intervals, sufficed to hold it in check.

The second patient was a servant girl, of twenty-three years, of a robust build, who had for some time been troubled with epileptiform attacks with disturbances of mind, apathy, hebetude, etc. The bromide of sodium associated with borax, was given without result. Various alopecic patches and red spots on the body leading to a suspicion of syphilis, an injection of the oil was made one morning. From the evening of the same day a profound change was observed in her symptoms. Her apathy and hebetude disappeared and she began to interest herself in her work. During the days following this amelioration persisted and her epileptiform seizures did not reappear. The injections were repeated every fifteen days. The patient left the hospital two months and a half after the first injection, completely cured.

The third patient, a woman of thirty-eight years and alcoholic, presented for about a year, slight epileptiform attacks and some symptoms of dementia. She also suffered from alopecia, which led to a suspicion of syphilis, in spite of absence of other symptoms. One single injection of the gray oil suppressed the attacks immediately. After two more injections, repeated at intervals of twenty-two, and nine days, all the cerebral symptoms disappeared. This certain and prompt action of the oil, in cases of cerebral syphilis lead the writer to suggest that it be employed as a means of diagnosis in subjects presenting epileptiform, comatose or other grave symptoms with an obscure origin.

---

CYSTITIS.

Dr. Luys (*Deutsche Medicinische Wochenschrift*, No. 35, 1893), in a case of tuberculous cystitis in which the urine was very purulent and bloody, and the patient was obliged to urinate every five minutes, with very violent pains towards the end micturition, employed instillations of sublimate, 5:100, according to Guyen's recommendation. To prevent violent pain cocaine was first injected. The first injection was followed by slight hematuria which soon disappeared. They were given every day. Great improvement soon set in so that he was forced to urinate only every half hour. During the following months they were given every second day, later every eight to fourteen days and, finally, every two months. His urine was clear and he was obliged to micturate every two hours, although he was not cured he was placed into a tolerable condition, at least.

Dr. Okleoblom (*Ibid.*), in cystitis, and especially in gonorrhœal vesical catarrh, recommends instillation by means of Guyen's syringe, every second to third day, of one to six cgms. (fifteen drops to a drachm and a half) of a solution of iodoform in ether and oil, 1:7:7. The pain and tenesmus cease at once.

---

TO DISINFECT SEWERS, WATER-CLOSETS, ETC.

In the (*Raccoglitore Medico*, No. 10, 1893), the following means of disinfecting sewers, drains, water-closets, etc., is recommended. Prepare as much quick-lime as desired, break it into small pieces and place it in liquid carbolic acid for a quarter of an hour, and then preserve it in a tightly-closed vessel. If one wish to disinfect a sewer throw into it a few pieces of the lime which will absorb dampness and send forth any quantity of vapor, impregnated with the carbolic acid, which will penetrate all through the sewer and disinfect it perfectly. Repeat it twice a day.

---

DYSPNŒA OF ACUTE PHTHISIS.

Dr Bernheim (*Deutsche Med. Wochenschrift*, No. 37, 1893) recommends in the dyspnœa of acute phthisis the following formula:

℞ Caffeine Citrate..... 2 gms. (grs. xxx).
Sulphuric Ether ..... 20 gms. (℥v).
Inject two grains (ℳ gtts). morning and evening.

---

**A Sign of Breech Presentation.**

When, in a woman who has passed the sixth month of pregnancy, a sharp pain is produced by placing the hand on the fundus uteri, it may be almost affirmed that there is a breech presentation. The fact is very frequent, although not constant, being present in about seventy per cent. of cases. The pain is sometimes spontaneous. How is it to be explained? According to Pinard, it is due to the irregular distention produced by the rounded mass of the head. If version is performed, the pain disappears.—*La Clinique Internal.*

## DIAGNOSIS OF DIPHTHERITIC ANGINA.*

Marfan (*Le Bull. Mèd.*, May 24, 1893), would enforce the following precept in infantile medicine. In the adult an examination of the throat is not necessary unless the patient complains of pain and pharyngeal dysphagia, or when there is some peculiarity in the clinical history as for instance when there is a suspicion of syphilis. In children, however, and especially in small infants, this examination of the throat should always be made whatever may be the trouble for which one is called in consultation and this exploration provokes ordinary cries and agitation which should be utilized to the end of the clinical investigation. The examination of the pharyngeal region will permit us to recognize whether an angina exists. This recognized it is necessary to establish a primary distinction; whether the throat is red or whether it presents on its surface a whitish layer. If it is red there is an erythematous angina present and the fear of diphtheria may be deliberately discarded. One has said, it is true, that diphtheritic angina may appear in two phases: an erythematous and a pseudo-membranous, and some physicians affirm to having seen the disease in the purely erythematous phase; but these affirmations are quite exceptional. If in doubt withhold the diagnosis a few hours when, if the case be diphtheritic, a whitish exudate will be produced. On the contrary, if it be found that the angina is accompanied by the presence of a whitish layer it is always necessary to think of diphtheria and the signs of this disease must be looked for.

There are two principal white anginas: 1. Follicular angina; 2. Pseudo-membranous angina. The *follicular angina* is characterized by the production in the crypts of the tonsil of a whitish material consisting of mucus epithelial cells and round cells. This has been called *cryptic* or *lacunar* tonsilitis. Its aspect is typical; on the more or less tumified and reddened surface of the tonsils may be seen small white spots, about the size of a millet seed. Each of these small spots represents the orifice of a tonsillar lacuna filled with the whitish exudate. Pressure with the finger upon the tonsil will cause this creamy material to exude. The exudate is not adherent. It is easily removed and often gives off an odor somewhat fetid. Placed in water it dissolves completely. In this form of angina the exudate primarily intra-cryptic may at times spread over the surface of the tonsils and give more or less thickness to the whitish spots, and these may even fuse; but nearly always the exudate does not escape the bounds of the tonsillar region to invade the folds of the palate or the uvula. Moreover, in no case may this white material be taken for a false membrane, because it may be readily removed, and dissolves in water.

*Pseudo-membranous* or *membranous angina*, is quite different from follicular angina. In the beginning there may be seen upon the two tonsils or upon one, a white spot, large. This may at first be readily detached from the tonsil to which it is adherent especially by intra-cryptic filaments; below the exudate the mucosa is red and a little abraded; around it the mucosa is swollen. This first white spot has a great tendency to spread; it does not remain limited to the tonsil but extends to the roof of the palate and its pillars, and down upon the surface of the uvula which may be covered as if by a glove. It also invades the posterior wall of the pharynx. White at first the false membrane becomes finally a dirty gray. Little by little it thickens, becoming more prominent and more adherent. If a piece be removed for examination it will be found to be quite adherent; cannot be scraped off, and will not dissolve in water; it is torn with difficulty; under the microscope it is formed mainly of fibrin and epithelial cells. Once removed it is reproduced nearly always with more or less rapidity, while the exudate of lacunar tonsillitis does not return after clearing a region. Bacteriological researches have shown that all of the pseudo-membranous anginas are not diphtheritic, that is to say, are not caused by the bacillus of Klebs. In other words a pseudo-membrane may be produced by other bacteria, the streptococcus, the staphylococcus, the pneumococcus, and by an unnamed coccus described by Roux and Yersin. In these cases the false membrane is indistinguishable from the diphtheritic membrane.

# ABSTRACTS.

## CONVULSIONS.

Dr. Charles G. Kerley in this article considers "that class of convulsions most frequently met with in children under three years of age, such as come on during apparent health or slight illness, rather than those which develop during or at the close of some serious disease. I know of nothing that will so quickly and thoroughly demoralize a family as the occurrence of an unlooked-for convulsion in one of the children.

A certain degree of fright on the part of the friends and relatives is to be expected, as the appearance of a child during a convulsive seizure is most alarming to those not accustomed to the sight. I am sure, however, that the fright and anxiety would be lessened to a great extent if the nature and termination of such convulsions were better understood, and if it were known that the cause in a large majority of the cases lies in the gastro-intestinal tract, due to an error in diet, and that the attack is not necessarily a symptom of brain disease, as is usually imagined; further, that nearly all such convulsions are entirely recovered from if intelligently managed. Nearly all of the attacks of this nature which I have seen occurred either in badly fed bottle babies, or in those beyond the bottle age who were given their food irregularly or in quality or quantity unsuited to their age. The custom in same households of giving the baby "just a little taste" of some forbidden food is not an infrequent cause of convulsions; the child is pleased with the new sensation, demands more, the "tastes" are repeated and trouble follows. In a few cases I have known a seizure to follow a single indulgence in cake, pie or fruit. I have seen but four cases in fairly well-managed breast-fed infants. In these, one attack followed a fall, the child having received the full force of the fall on the head; in the second, it was the initial symptom of lobar pneumonia; the third was a case of infantile paralysis in which convulsions attended the acute stage; in the fourth, convulsions resulted from a profuse cerebral hemorrhage. In a case occurring under my care an eighteen-months-old-girl had repeated convulsions. The mother supposed teething to be the cause and was frantic because I refused to lance the perfectly healthy, innocent gums; there was no sign of a tooth coming through. After a large dose of castor oil had been given, the patient passed one-eighth of an orange.

Children with rickets are especially predisposed, and an indiscretion in the diet which in a healthy child would produce no discomfort may bring on a violent attack in one so affected.

Teething as an exciter is generally supposed to play an important rôle. This process as a direct cause, through the irritation produced by the direct pressure of the teeth on the gum can, in my opinion, be excluded entirely. Between nine hundred and one thousand infants have cut their teeth while under my care, some of whom had convulsions while teething, but in not a single instance was the teething process a direct cause. Thorough investigation of the circumstances attending the attack and examination of the patient would reveal the true seat of the trouble, which was usually found in the alimentary tract. Had these teething babies been examined only superficially, or had they not been examined at all, as is too often the case, the cause would most certainly have been ascribed to the teeth.

A very interesting case in a child under one year of age was reported several years ago in the London *Lancet*. A long hair became fastened between two teeth and hung down the throat; the irritation of the alimentary tract thus produced caused repeated attacks until the hair was discovered and removed.

Convulsions may occur in the very young and weak as the result of heat prostration. Worms are mentioned as a fruitful cause. I have seen but one case of this nature, in a strong boy of three years. That he should show marked nervous disturbance is not surprising, as vigorous, well-directed treatment removed forty large round-worms during the next three days.

Lobar pneumonia is sometimes ushered in with convulsions, but this occurs far less often than we would be led to suppose.

Among seventy-five cases which I have had the opportunity to observe, convulsions were the inital symptom in but three. The onsets of the brain diseases known as simple and tubercular meningitis, according to my experience, rarely occur with convulsions; they are, of course, a common symptom of these diseases, but usually appear after a period of illness, the symptoms of which are very often diagnostic of serious brain disturbance before the advent of convulsions.

Cases have been reported which were supposed to be due to the irritation produced by unsuitable, tight or ill-fitting clothing, this is certainly not a very common cause; if it were the physicians of this country would be fully occupied caring for infants with convulsions.

The question is often asked, can a child inherit a tendency to convulsions? The offspring of the epileptic and the neurotic are certainly predisposed. The decidedly ancient notion than an infantile eczema should not be treated and cured because it may "strike in" and produce convulsions is too absurd to deserve further mention.

Simon believes that 80 per cent. of the attacks occurring in young children are due to digestive disturbances. Concerning the entire number of cases seen by me, 80 per cent. were due to simple digestive trouble. Besides those occurring during brain diseases, quite a number developed during whooping cough complicated with broncho-pneumonia. Many of the fatal cases of inflammation of the bowels have convulsions late in the disease, death frequently occurring in the attack. I have also seen a few cases occur during scarlatina, measles, malaria, diphtheria and Bright's disease. As regards these cases, however, which come on during apparent health or slight illness, fully 95 per cent. were due to some disturbance in the stomach or intestines. With proper feeding, bathing, clothing and fresh air, the chances of convulsions are very small indeed.

What is to be the management of a child if attacked? The family physician must be summoned at once, a hot mustard bath should be arranged as soon as possible into which the child is placed and kept from ten to thirty minutes, by which time the seizure will ordinarily have passed off, and the child will make known its return to the normal condition by crying. As soon as swallowing is possible give from 1 to 2 teaspoonfuls of castor oil, according to its age; in case vomiting follows, it may relieve the stomach of offending material; if the oil is repeated in a few minutes with a few drops of whiskey added, it will almost always be retained. When the patient is removed from the bath, rub him vigorously until dry, put him in his crib and apply cold cloths to the head; do not hold him on the lap. The room should be cool, darkened slightly, and the patient kept absolutely quiet. If the bowels do not move in a reasonable time, a large warm-water enema should be given. The enema should be given as soon as, or even before, consciousness returns, if there has been habitual constipation, or if the abdomen is at all distended.

The management during the few days following the attack it important. Light and easily digested food must be given—preferably fluids; the bowels should be carefully looked after and all means of excitement avoided; plenty of fresh air is also of benefit. The physician should always be sent for, no matter how light the attack, as it is very apt to be repeated if the cause is not discovered and removed."—*Mother's Nursery Guide.*

### The New Entries at the London Medical Schools.

The following is the latest list of new entries at the medical schools in London for the session 1893–94 in the order of precedence: Guy's 238, St. Mary's 164, University College 164, the London 157, St. Bartholomew's 156, King's College 119, St. Thomas's 94, Middlesex 69, Charing Cross 58, Westminster 36, St. George's 27. At the provincial schools the following entries have been returned: Owens College 261, Durham 176, Cambridge 132, Mason College 94, Yorkshire College 68, Bristol Medical School 36, Sheffield Medical School 14.

---

*The Chicago Clinical Review* has inaugurated a new department in the current number. That is a list of titles of the original articles and leading editorials that have appeared in the medical periodicals of the month.

# THE LIBRARY TABLE.

## BOOK REVIEWS.

*A System of Genito-Urinary Diseases, Syphilolgy and Dermatology.* By various authors. Edited by Prince A. Morrow, A. M. M. D. Clinical Professor of Genito-Urinary Diseases, formerly Lecturer on Dermatology in the University of the City of New York; Surgeon to Charity Hospital, etc; with illustrations. In three volumes. Vol I, Genito-Urinary Diseases. New York: D. Appleton & Co., 1893.

One of the first things that strikes the reviewer is that the articles are written by men whose opinions are of value, and that what they have said they have said well. The articles represent the latest thought on the various subjects and are not, as is too often the case, merely a job lot of old essays long since out of date, dignified by the name of "system." Care has been taken by the editor that each author should keep strictly to the limits assigned to him, and as a result there is little of that overlapping of articles so common in works of this kind.

Not the least of the many attractions of the book is the press work of which the publishers may well feel proud. Good paper, clear type and sharp illustrations render the volume pleasing to the eye and add to its usefulness. Especially beautiful are the colored plates, several of which are scattered thoroughout the book.

The work is the result of the labor of thirty-two contributors. Dr. George Woolsey describes the Anatomy and Physiology of the Genito-Urinary Organs in a carefully written and well illustrated article. To Dr. Ramon Guiteras has been assigned the duty of contributing the article on Diseases of the Penis, while the section on Diseases and Injuries of the Urethra is from the pen of Dr. F. Tilden Brown. Both articles are concise, well written and amply illustrated. The subject of Urethritis is divided into three chapters, Dr. S. Lustgarten discussing the Etiology of the disease in a scholarly manner. The various micro-organisms found in the urethra as well as the true gonococcus of Neisser are fully described and the various methods of staining and culture discussed. The various urethral discharges other than gonorrhœal receive brief mention. Dr. George Emerson Brewer contributes the chapter on Acute Urethritis, while that on Chronic Gonorrhoea is from the master hand of Dr. William K. Otis. Stricture of the Urethra is handled by Dr. J. William White in his usual clear and decisive manner. Especially fine is the article on Stone in the Bladder by Dr. Arthur T. Cabot. The various operations are carefully and clearly described as well as the older methods of dissolving the calculus by medicinal agents. Dr. Morrow, beside his work as editor, has found time to contribute an interesting and valuable article on the Functional Disorders of the Male Sexual Organs. Varicocele is ably dealt with by Dr. Edward L. Keyes, and the chapter on Gonorrhœa in the Female is furnished by Dr. Andrew F. Currier. The remaining articles in the volume are by men equally capable and the whole work is one that American authors and physicians may well be proud of.

In the volume there is little for the critic to carp at. Dr. Otis advocates dilatation of the urethra in gleet so soon as the subacute stage occurs and advises incision of the meatus in order to accomplish this. The operation has been condemned by many on account of the flaccid condition of the meatus which results and the often uselessness of the procedure. Gonorrhœal Rheumatism is still left by Dr. Frank Hartly as an reproach to medicine so far as the treatment by drugs is concerned. Dr. Wyeth, in his article on Hydrocele, advocates the old treatment of tapping and injecting of the sac, making no mention of the more modern method of incision and packing. Again, Dr. Keyes, in speaking of the open treatment of Varicocele, says "I consider it obsolete and shall not describe it." In view of the fact that many surgeons still employ this method, it seems as if it would have been better had he at least described the operation.

The editor has stated in the preface that "The articles are all of the most practical character and appeal directly to the needs of the general practitioner, to whom they will be found to be of the greatest value; as they are epitomes of all that is known on the respective subjects up to the date of the issue of the work," and the implied promise is fully kept.

If the same high standard is maintained in the remaining volumes on Syphilology and Dermatology, the general practitioner and specialist alike will find the work invaluable.

---

*The Medical News Visiting List* for 1894. Weekly, dated, for 30 patients); Monthly (undated, for 120 patients per month); Perpetual (undated, for 30 patients weekly per year); and Perpetual (undated, for 60 patients weekly per year). The first three styles contain 32 pages of data and 176 pages of blanks. The 60-Patient Perpetual consists of 256 pages of blanks. Each style in one wallet-shaped book, pocket, pencil, rubber, and catheter-scale, etc. Seal Grain Leather, $1.25. Philadelphia: Lea Brothers & Co., 1893.

This *Visiting List* for 1894, has been thoroughly revised and brought up to date. The text portion contains useful data for the physician, including an alphabetical Table of Diseases, with the most approved Remedies, and a Table of Doses. It also contains sections on Examination of Urine, Artificial Respiration, Incompatibles, Poisons and Antidotes, Diagnostic Table of Eruptive Fevers and the Ligation of Arteries. The classified blanks are arranged to hold records

of all kinds of professional work, with memoranda and accounts. Four styles are now published: Weekly (dated, for 30 patients); Monthly (undated, for 120 patients per month, and good for any year); Perpetual (undated, for 30 patients weekly per year); and Perpetual (undated, for 60 patients weekly per year). This last style consists of 256 pages of assorted record blanks, without text. Each style is in one volume, bound in handsome red leather, with pocket, pencil, rubber, and catheter-scale, price, $1.25. When desired, a Ready Reference Thumb-letter Index is furnished at an additional cost of 25 cents.

---

*Duane's Students' Dictionary of Medicine.* The Students' Dictionary of Medicine and the Allied Sciences. Comprising the Pronunciation, Derivation and Full Explanation of Medical Terms, together with much collateral descriptive matter, numerous tables, etc. By Alexander Duane, M. D., Assistant Surgeon to the New York Ophthalmic and Aural Institute; Reviser of Medical Terms for Webster's International Dictionary. In one square octavo volume of 658 pages. Cloth, $4.25; half leather; $4.50; full sheep, $5.00. Philadelphia, Lea Brothers & Co., 1893.

This work is the result of the painstaking labor of an author abundantly qualified for the difficult task. The volume is one of merit, and will compell recognition as a standard medical dictionary for students.

Dr. Duane's experience and scholarship are sufficiently attested by his position as Reviser of Medical Terms for *Webster's International Dictionary*. In the present work he has undertaken to provide medical students with full information concerning every word they will meet in acquiring their professional education. The vocabulary is liberal, and its fulness is paralleled by the treatment accorded to each word. The definitions are of the "explanatory" style, including not only a statement of meaning, but likewise much descriptive matter under headings which would be inadequately represented by a definition however full. Thus, under diseases are given causation, symptoms and treatment; under important organs, outlines of structure and functions; under drugs, actions, uses and preparations, the information being arranged so as to give a rational and connected idea of the subject. Extensive tables of bacteria, muscles, arteries, veins, nerves, etc., are included. Each word is followed by its correct pronunciation given by means of a simple and obvious phonetic spelling. Derivation, an unexcelled aid to remembrance of meanings, is likewise fully and clearly stated, Greek letters being replaced with those of the English alphabet, for the convenience of those unfamiliar with Greek. The type has been carefully selected for legibility, and each page contains an extraordinary amount of matter.

*Sonsino, P.—Sviluppo, ciclo vitale e ospite intermedio della Bilharzia haematobia.* (Proc. verb. della Soc. Tosc. di scienze nat. addun. di 11 agosta 1893. 1 p)

(The life history of *Bilharzia haematobia.*)

Among the flukes which are found in the human body there is one species which is particularly interesting from several points of view. It is interesting to the physician because it is one of the most injurious parasites found in man. It lives in the veins and causes the disease known in Egypt and various other countries where it occurs, as Bilharziosis. It is of special interest to the zoologist because it is the only fluke found in man in which the sexes are separate. *Fasiola hepatica*, *Distoma sinense*, *Distoma lanceolatum* and the others all being hermaphrodites.

For some years zoologists have speculated and experimented upon the life-history of this parasite. Cobbold attempted to inject various mollusca, crustaceans and insects with the embryonic stage. Harley thought this species might develop without any intermediate host and attempted to infect dogs and cats by feeding the ciliated embryos to them, but his results were negative. Sonsino then experimented with various mollusca and insects but did not succeed in solving the question of the life-history of the parasite. This last summer, Sonsino again experimented with the parasite, and this time seemingly with better success. His results may be summed up as follows:

The life-history of *Bilharzia hæmatobia* is quite different from that of other trematodes.

It consists of a metamorphosis with change of host but without alteration of generations. The intermediate host is a small crustacean. The miracidium (embryo) of *Bilharzia* bores into the crustacean, loses its cilia and becomes encysted. When the crustacean is swallowed in the unfiltered drinking water by persons, the parasite is freed from its cyst, bores its way to the portal vein and completes its development to the adult stage.

A similar parasite (*bilharzia crassa*) occurs in cattle.

---

### The Use of Mono-Bromide of Camphor in Vertigo Epilepsy.

Dr. Bourneville (*Le Progres Medical*) has used this remeay for twenty years in the treatment of epilepsy when vertigo is a frequent complication. Five cases are reported showing the results of administration. The daily dosage is from three to seven capsules, each containing three grams of the remedy. Each week the daily dose is increased by one capsule until the maximum is reached, when the treatment is omitted for a week, to be resumed in the form of a daily dose of three capsules.

---

### Salicylate of Soda per rectum.

In all cases where salicylate of soda disagrees with the stomach, it be administered per rectum without any difficulty. In the clinic at Munich; after an evacuating enema, the following mixture is injected pretty high up in the bowel: one and one-half to two drachms of solicylate of soda; water, three ounces, and a pretty large dose of tr. opii to prevent irritation of the bowel.

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

THE EDINBURG MEDICAL JOURNAL for November contains a continued article on

**The Disorders of Speech,**

by Dr. John Wyllie. In speaking of motor aphasia and quoting Trousseau, he says: "The greater number of aphasics are paralyzed in the right hand and cannot write; and if they acquire the habit of writing with the left hand, it is easy to see that they cannot trace, in writing, many more words than they can express in speech." In some cases, however, patients presenting typically the symptoms of motor aphasia in their speech, can yet express themselves correctly in writing. In these cases it is believed that the lesion is not cortical, but sub-cortical; and that it is so situated as to cut across the pathways leading to the organs of phonation and articulation, whilst it leaves intact the pathways connecting the motor speech centres with the centres for writing. The author thinks it far from certain that this exceptional retention of the power of writing is to be always so explained, and asks if it is not possible that the patient was markedly *auditif*, and that his vivid auditory word images were in themselves sufficiently potent to call up the equivalent visual and motor images in the writing centre. The reception and interpretation of audible speech are little, if at all, interfered with; but in the majority of cases, there is an interference with the power of reading.

When motor aphasia is complete, the power of repeating or echoing spoken words is of course destroyed as completely as is the power of volitional or spontaneous utterance. In both cases, the power of utterance would be lost permanently were it not for the further education of the convolution on the other side of the brain.

As to copying of written or printed words, it is not materially interfered with.

Other phenomena associated with it are amimia and paramimia and also sometimes an inability to protrude the tongue by effort of the will.

In training a patient with motor aphasia to speak, it is often of advantage to him to pronounce simple words in his hearing and ask him to repeat them. Let him master the letter sounds first. In this way, in many cases the patient re-acquires the power of speech.

Quoting Wernicke, the author says of conduction aphasia, "The patient understands everything, he can also say everything, but the choice of the right words is disturbed.

The autopsy on a case of this kind revealed the chief lesion to be a softening with depression in the island of Reil and the floor of the sylvian fissure.

Dr. A. G. Miller reports a

**Case of Facial Neuralgia Treated by Operation.**

The neuralgia originated in the stump of a molar of the upper jaw, the pain was typically explosive and manifested itself mainly in the infra-orbital nerve although the other divisions of the fifth nerve were affected. At the first operation he cut down over the infra-orbital foramen and stretched the nerve. This relieved his patient for a time but the trouble returning he cut down and exposed the infra-orbital foramen and nerve, opening into the antrum without opening the mucous membrane, breaking up the lower wall of the infra-orbital canal, and drawing out the nerves, which gave way. The end was then cauterized with a small wire.

After even this more radical operation some trace of the trouble returned and the author believes that any operation, however radical, is only palliative at the best.

**Chemical Examination of the Contents of the Healthy Stomach,**

by Alex. L. Gillespie. The conclusions he draws are as follows:

1. Free Hcl. is secreted by the stomach glands from the moment at which food enters the viscus.

2. First stage of gastric digestion, during which no free Hcl. is present, but the total acidity constantly rises.

3. Free Hcl. appears in the stomach contents between the first half hour to the second or third hour.

4. Second stage of gastric digestion, both free and combined Hcl. present. Acidity rising.

5. Third stage, both free and combined Hcl. present. Total acidity falling.

6. The acidity during the earlier part of the first stage is so small that it can probably allow the amylolytic action of the saliva to 9 per cent. on for a short time.

7. The free Hcl. secreted at first combines at once with the proteids in the food.

8. Hcl. originally combined is less antiseptic than pure Hcl.

9. The total solids, both of the filtered and unfiltered contents, fall per cent. from the commencement.

10. The total acidity is lower in the filtered contents; the combined is generally higher, the free lower, than in the unfiltered.

11. The inorganic salts diminish per cent. from the commencement.

12. There is generally an excess of fixed chlorides at the beginning of digestion.

13. The total proteids per cent. in solution fall during digestion.

14. Albumen, probably nucin, increases per cent.; albumosis remain stationary, while the peptones diminish largely per cent.

15. The Micro-organisms are present in large numbers at the beginning of digestion; the numbers diminish as digestion goes on.

16. The stomach contents have no further digestive power unless there be some free Hcl. present.

17. The free Hcl is seldom over .09 per cent. at any hour after a proteid meal. It may

rise to .162 or .27 after a meal chiefly carbohydrate in character.

18. Hcl combined to proteids does not cause heartburn, at least to any appreciable extent, but both free Hcl. and free organic acids do so, the latter especially.

19. The pain which comes on immediately after food has been taken is probably due to the presence of an ulcer, or of erosions or is neurotic in origin. Coming on at the time when free Hcl should appear in the contents, this acid is probably the offender.

If accompanied with flatulence and heartburn, and occuring at variable times after taking food, the author would suspect some fermentation, and, if carbohydrates are badly borne, diminution in the secretion of Hcl. as well.

Deficiency of Hcl. is easily remedied for a time by the administration of some acid by the mouth. Hyperacidity is difficult to treat, and the other organs should be carefully looked into. The diet should be non-irritating.

When the stomach is dilated or the seat of a chronic gastritis, regular lavage gives good results. In gastric ulcer, treat the hyperacidity and if the patient be fed by the bowel, the administration of a little grated meat or albumen water by the mouth will often allay the pain. He believes washing out the stomach in ulcer is followed by relief.

Dr. N. T. Brewis has an interesting article on

**Patrotitis following operations on the Abdomino-Pelvic Organs.**

He reports a case in which an ovariotomy was followed on the fifth day by swelling in the parotid region. The gland was opened and drainage practiced and the patient made a good recovery.

He thinks we may regard the parotitis which comes on after operation on the sexual and abdominal organs as the result of a reverse sympathy. That cases which run through a course like mumps, ending in resolution, are due to this nerve connection alone; but that those cases which suppurate while sharing the sympathetic relation, must, from the number of fatal results which occur, be regarded as involved in septic intoxication. In suppurative cases which do not terminate fatally he considers that the septicæmia has exploded in the parotid gland.

**What is the Best Treatment of Diphtheria**

by Dr. Keith Forman MacDonald. He considers that the success we obtain in treating this disease largely depends upon how well our directions are carried out, and how the remedies are used. He relies mainly on the following, when the case is a mild one: an aperient, hot fomentations to the throat, the steam of hot water and the spray of lactic acid and lime water or sulphurous acid and water, a chlorate of potash drink, and a diet of milk and beef tea. When the case is at all severe he gives iron and quinine internally 15 to 20 minims of the tincture of the perchloride and 1 to 5 grains of quinine every four hours. Locally he applys a solution of equal parts of the tincture of the perchloride of iron and glcyerine every four hours, at the same time he uses the lactic acid and sulphurous acid spray alternately several times a day For disinfecting the room and articles of clothing he uses carbolic acid, chloride of lime, Condys fluid and fuming sulphor.

The remaing papers in this issue are "The Etiology of Ectopic Gestation" by Dr. J. C. Webster. "Studies in Fœtal Pathology and Teratology," by Dr. J.W. Ballantyne. "Notes on a Case of Tetanus," by Dr. J. W. Dowden and a continued article on "Varieties of the Appendix Vermiformis, Cæcum, and Ilio-Colic valve in Man," by Dr. John Struthers.

---

THE AMERICAN JOURNAL OF OBSTETRICS

for November.

This issue of the journal contains four papers on hysterectomy. The first contribution on the subject is by Dr. J. M. Baldy and is entitled

**Hysterectomy. Its Indications and Technique.**

According to the author, the indications for the operation are :

1. Malignant degenerations of the uterus.
2. Fibroid tumors of the uterus.
3. Pelvic inflammations.
4. Prolapse of the uterus.
5. Inversion of the uterus.

In regard to fibroid tumors, the author is of the opinion that if small and giving rise to no untoward symptoms they should be left unmolested, provided the patient is not exposed by her station in life to attacks of inflammation and is living in such a neighborhood that competent surgical aid can be obtained if necessary. If the patient be within a few years of the menopause it may be advisable to adopt for the time being the expectant line of treatment. Under all conditions a fibroid tumor of the uterus should be subjected to surgical treatment and the author believes that hysterectomy is the proper procedure to adopt. Myomectomy can only be considered where the patient is of such an age as to make it desirable and possible for her to bear children and where the uterine appendages are healthy and capable of performing their function ; the reverse of which is true in the majority of fibroids.

In pelvic inflammations, Dr. Baldy believes that hysterectomy should be the operation of choice in all cases in which the uterine walls are infiltrated with pus and the uterus materially enlarged. All cases of prolapsus uteri, in which the usual surgical means have been tried and failed, should be subjected to hysterectomy as a sure means of cure. The operation should always be followed by plastic operations on the anterior and posterior vaginal walls for the repair of the relaxation of the vagina.

The author believes that the combined method of performing hysterectomy is superfluous and more dangerous than either the vaginal or abdominal operation alone. Vaginal hysterectomy by means of the catgut ligature has, in the author's hands, proved the safest and most satisfactory of the vaginal operations.

The author also thinks that, in abdominal hysterectomy, the dropping of the stump back into the pelvic cavity is preferable to the extra-peritoneal method. He is also strongly in favor of the supra-vaginal amputation as against total extirpation. The technique of the operations are described and the various steps illustrated. The author advises the Trendelenberg position in performing abdominal hysterectomy.

The second paper is by Dr. George M. Edebohls on

**The Technique of Total Extirpation of the Fibromatous Uterus.**

When treatment is called for, the author believes that surgery is invariably to be preferred to any and every other method of therapeusis. The method of operating which the author prefers is as follows : The patient is placed in the lithotomy position and the vagina and uterus carefully disinfected and the uterine cavity and vagina packed with antiseptic gauze. The position of the patient is then changed to the Trendelenburg posture. The tumor is delivered through the abdominal incision and pulled as far as possible out of the pelvis. A transverse incision is made through the peritoneal covering of the anterior and posterior surfaces of the uterus from one broad ligament across to the other. The two peritoneal flaps thus marked out should be large enough to easily cover the defect in the pelvic floor left after the removal of the uterus. The peritoneal flaps are next stripped from the surface of the uterus. In doing this the bladder and ureters are carried forward with the anterior flap well out of the way of harm during the further steps of the operation. The uterine artery on either side is next secured by a subperitoneal mass ligature of stout catgut, carried well down to but not into the vagina. The broad ligaments are tied off by two further catgut ligatures on either side, one embracing the round ligament and the other the infundibulo-pelvic ligament and the spermatic artery. The cutting-out of the uterus, tumor, and appendages in one piece between the ligatures is now an easy and bloodless procedure. The six ligatures are cut short and the knots turned downward toward the vagina and the gap in the pelvic floor closed by uniting the anterior and posterior flaps by means of a transverse, running Lembert suture of catgut, extending from the stump of one infundibulo-pelvic ligament across to that of the other. The peritoneum is dry-cleansed with sterilized gauze, the abdominal wound closed without drainage, and the patient returned to the lithotomy position. The gauze packing is removed from the vagina and replaced by a loose dressing of gauze applied in such a way as to drain the supra-vaginal subperitoneal space.

The author believes the method to possess the following advantages:

1. The danger of infection from the uterus and vagina is entirely avoided, or at least minimized.

2. The uterine arteries are secured with ease and certainty. The distension of the vagina by the gauze packing enables the operator to carry the mass ligature well down to the vagina and to include the supply to the upper end of the vagina as well, so that there will be no bleeding of the vaginal arteries after cutting out the uterus.

3. The operation is practically bloodless. With the exception of the incision through the peritoneum fore and aft, no part is divided until its blood supply has been secured.

4. The danger of wounding the bladder or uterus is reduced to a minimum. These organs are lifted with the anterior peritoneal flap well out of the field of operation.

5. The closure of the peritoneum is as perfect as it can be made, its *status qu ante* is restored, and no foreign body is left in its cavity.

6. The after-treatment required is practically *nil*. The patients have generally left bed at the end of two, and hospital at the end of three weeks.

The third paper is by Dr. E. E. Montgomery and deals with

**Vaginal Hysterectomy.**

The author points out clearly the indications for the operation and the symptoms which should lead the practitioner to look for diseased conditions of the uterus requiring surgical interference. He urges that a thorough examination be made in any suspected case and the operation performed at as early a period as possible, if disease exists. In the preparation of the patient for operation the author urges that the patient be subjected to antiseptic vaginal douches, and that, several days before operation, the vagina should be carefully cleansed with a solution of creolin and tincture of green soap, and the diseased tissue carefully cut away with a sharp curette and scissors, the cavity and vagina irrigated with a hot sublimate douche 1: 2000, dried, and packed with iodoform gauze. Later this packing should be removed, the vagina cleansed and repacked. The latter packing may remain till the time of operation when it should be removed and the cavity and external surfaces carefully cleansed with the creolin and soap solution and finally irrigated with hot sterilized water. The external surfaces should have previously been shaved.

The author prefers the clamp to the ligature in securing the broad ligaments for the following reasons:

1. Its ease of application, enabling the operator to economize valuable time.

2. The greater security against hemorrhage —the ligature, though apparently securely tied, may slip from the stump when the latter shrinks after the removal of the uterus.

3. We have no infected ligature to complicate or delay the subsequent convalescence.

4. By traction upon the clamps we are enabled to carry the gauze tampon above the lacerated surfaces and pen the intestines within the peritoneal-lined cavity, thus affording ready exit for the sloughing tissue devitalized by the pressure of the intruments.

The author reports twenty-one operations performed with twenty-one recoveries and concludes from this showing that the operation certainly cannot be a very dangerous one.

The fourth paper is by Dr. Joseph Price on

**The Extra-peritoneal Treatment of the Stump in Supra-vaginal Hysterectomy.**

In this paper the author makes an urgent plea for the use of the nœud in hysterectomy. The objections to its use are carefully considered and answered. He declares that a proper pedicle can always be made and the operator who cannot do so is not competent to perform the operation. He condemns the use of multiple ligatures in the pelvic cavity as adding to the gravity of the operation. He affirms that the nœud should never slip and that the bowel should never be included in its grasp and also that by care the bladder and ureters ought never to be involved. He is convinced that if for any reason it is concluded that the nœud cannot be, complete extirpation is likely to be the safest resort and therefore the one to be selected. Results and statistics are wholly in favor of the extra— and supraperitoneal operation and clean extirpation. The latter procedure he does not oppose, having performed it successfully, but he considers that the risks are greater than in the old and established procedure.

[Judging by Dr. Price's statistics, the operation by means of the nœud in his hands is a most satisfactory procedure however far it may fall short of being an ideal one.—Ed.]

Dr. Henry J. Garrigues contributes a paper on

**Symphysiotomy.**

The space gained, the limits and indications as well as the technique of the operation are all carefully considered by the author in the paper. He regards the subcutaneous incision as the best and would resort to the open method only in case of uncontrollable hemorrhage, if the repairs of injuries demand it, or the symphsis cannot be cut. The suturing of the ends of the bones with silver sutures he regards as superfluous and an unnecessary complication of the operation. The soft parts, skin and adispose tisspe should under all circumstances be united by deep and superficial silk sutures, which are left in for a week or ten days. Drainage he considers to be superfluous. In order to keep the two halves of the pelvis together nothing is better than rubber adhesive paster. While the straps of adhesive plaster are being applied, and during after-treatment, the patient should lie with outstretched legs, the knees together, and the feet turned inward, as this position of itself approximates the ends of the bones

In regard to maternal injuries, the author believes that the protection of the vagina with a vectis-like instrument, as proposed by H. W. Freund, is not practicable. The placing of the hand between the bones, as recommended by Schauta, seems to the author to be more likely to increase the tension than to lessen it. The chief thing, he believes, is to extract very slowly and in the right direction. If injuries occur they should be repaired immediately with silk or catgut sutures. If there is a tear in the bladder it should be closed with continuous tier catgut sutures, one applied to the mucous membrane the other to the muscular coat and the peritoneum.

In regard to the relation of symphysiotomy to other obstetric operations. Cranotomy on the living child, or what is worse, expectation till the child is dead, followed by craniotomy, ought never to be thought of in any community in which it is possible to obtain the assistance of a man capable of performing symphysiotomy. As to the induction of premature labor, in cases in which the mother's life is to be preferred, induction of premature labor retains its position; but in others, in which the life of the child is of particular importance, symphysiotomy is to be preferred, the infant mortality being only about half as large as in the other operation. In regard to its relation to Cæsarean section, the author concludes, after reviewing the statistics, that with proper regard for the life of the mother there can be no hesitation in regard to the preferability of symphysiotomy. The operation competes with the Porro operation, as it has been safely performed after the woman has been many days in labor. Any form of Cæsarian section ought therefore, to be confined to the cases in which the coarctation goes beyond the limits for symphysiotomy. Even difficult forceps and version operations ought to be replaced by symphysiotomy, and if the child were unusually large the operation would be indicated even with a normal pelvis.

In the author's opinion symphysiotomy is a valuable addition to obstetrical resorrces, which ought to be performed frequently in maternities and in private specialist practice.

Dr. A. W. Abbott contributes a paper on

**The Co-ordination of the Muscles Closing the Urethra Vagina and Rectum, and its Application to the Precise Diagnosis and the Surgical Treatment of Injuries to the Pelvic Floor.**

The author gives the following rule for ascertaining what muscle or muscles of the perineum are torn. The patient is placed in the lithotomy position with the perineum exposed. If the patient alternately contracts and relaxes the sphincter ani, all the other muscles involved contracting and relaxing at the same instant, it will be immediately apparent, by touching the normal positions of the various muscles, which ones contract throughout their full extent and are therefore intact, and those that are torn by the partial or total loss of contractile hardening at the point of rupture. The exact site of injury may often be made out by sight alone, the sound side drawing up, while the tissues of the injured side are carried toward the uninjured side instead of counteracting the effect of the latter as they normally should. Having definitely located the injury, the technique of the operation is simple. Incise the mucosa and dissect down to the torn ends of the muscle. Place stitches so as to draw the ends of the muscle together. If the rupture involves only the transversus perinei

a small transverse incision will suffice. If the pubic part of the levator ani is ruptured the incision should be in the sulcus and the dissection carried down to the plane of the levator, in some cases as far as the posterior plane of the rectum, and the muscles exposed and drawn up with catch forceps; tendon or well-chromicized catgut should then be passed so as to get a deep and secure hold upon the muscles. It is usually necessary to dissect up the outside mucosa and fascia, so as to get as good a point as possible for the new insertion of the muscle. Should it be necessary, the operation may be completed by Emmet's operation.

Dr. Edward W. Jenks discusses the subject of

**Perineo-vaginal Restoration.**

Four important ends are to be attained in repairing the class of injuries under consideration: 1. To restore the loss of power and function to the lower portion of the rectum and vagina. 2. To restore the normal sustaining quality of the posterior vaginal wall for the anterior vaginal wall and bladder. 3. To provide as much support for the uterus as the perineum naturally gives. 4. To cure the many distressing nervous accompaniments. The operation he advocates is of the flap-splitting variety, or submucous dissections, advocated by Mr. Tait. For suturing material he prefers silkworm gut, which possesses the principal advantages of silver wire and is not so unyielding. The author especially directs attention to the following points:

1. Any single mode of operating is not adapted to every case of laceration of the perineum.

2. All other qualifications being equal, that surgeon will be the most successful in this class of operations who, instead of following hard-and-fast rules, possesses a mechanical skill which he can adapt to the peculiarities of each individual case.

3. The subsequent comfort of the patients is not facilitated by the superabundance of cicatricial tissue within the vagina; therefore the anterior wall, instead of being subjected to any surgical procedure for redundancy, should be sustained by a restoration of the normal posterior wall.

4. The surgical operation advocated by the author has for its object a restoration of the torn posterior vaginal wall and perineum to their normal condition and functions, whereby there is afforded (a) support for the uterus to the full extent provided for in the vaginal walls; (b) support for the anterior vaginal wall and bladder; (c) support for the lower end of the rectum.

The article is illustrated by wood-cuts showing the various steps of operation advocated by the author.

Dr. Hugh Hamilton describes "The Application of Graphics to the Fœtal Heart Sounds," by means of an instrument on the principle of the telephone but so designed as to record the tracings of the maternal and fœtal heart sounds on blackened paper by which means they can be differentiated and compared. The article is illustrated by a cut of the instrument referred to, showing its application.

The remaining papers in this months issue are: "Recent Surgical Advances and their Relation to Conservative Obstetrics," by Dr. W. Reynolds Wilson; "The Pathology and Treatment of Puerperal Infection," by Dr. Edward A. Ayers; "Exophthalmic Goitre," by Dr. Edmund Lee Tompkins; "Two cases of Phlegmasia Dolens," by Dr. J. T. Winter; and the "Inaugural Address before the Section on Obstetrics of the First Pan-American Medical Congress," by Dr. Giles S. Mitchell.

---

**Plaster of Paris as a Means of Filling Defects in Bone.**

Dr. H. Dreesmann in eight cases has filled cavities in bone, of small size, with Plaster of Paris, closing the soft parts over it and succeeded in healing six without fistula. The plaster was mixed with a 1 in 20 carbolic acid solution. The bone cavities after thorough mechanical removal of infected tissue were filled with olive oil and the latter heated by plunging into it the tip of the thermocautery. The practical advantages of the method over decalcified bone implantation seem doubtful, although the earliest cases remained well when last seen six months after operation.—(*Ueber. Knochenplombierung, Dr. H. Dressmann, Beitrage sur Klin. Chirurge* ix, 1893, p. 804.)

**Of Interest to Travelers.**

The Baltimore and Ohio Railroad announces that they have placed on sale round trip tickets at reduced rates to the Winter Resorts in Florida and the South, and also to such points of interest as Luray, Natural Bridge and Gettysburg. This company has also arranged to place on sale excursion tickets to San Francisco and other points in California on account of the Mid-Winter Fair, at unusually low rates. Excursion tickets are now on sale to Baltimore and Washington via the famous Royal Blue Line.

With its vestibuled train service via Washington to Cincinnati, St. Louis and Chicago, the B. &. O. is in the best of condition to handle western and southern travel. That the line is a popular one, is attested by the immense World's Fair business handled this summer.

Those contemplating a trip west or south this winter, should write to James Potter, Div. Pass. Agent, B. & O. R. R., 833 Chestnut St., Philadelphia, Pa., for rates and other information.

## ORIGINAL ARTICLES.

### ABSCESS OF THE LIVER; OPERATION; RECOVERY.

G. FRANK LYDSTON, M. D.,* Chicago, Illinois.

While abscess of the liver is by no means a frequent disease in temperate climates, it occurs with sufficient frequency to lack the element of novelty, were it not for the fact that an early diagnosis followed by operation and leading to the recovery of the patient is rather exceptional. The history of the case which I am about to relate is interesting in many respects. The patient, a strong, athletic man of 53 years of age, first consulted me on the 20th of May. I had known the gentleman for 10 or 12 years, during which time I had never attended him professionally, and he had never been to my knowledge seriously sick. His history for many years had been that of a healthy man with one exception, which was that during a violent fit of coughing in the course of an attack of so-called bilious fever and pneumonia, thirty years ago during the civil war, he had apparently wrenched himself in the epigastrium. Since that time he claimed that he had been conscious at times of a feeling of weight and soreness in the epigastrium, and from time to time he had suffered from attacks of what had been pronounced gastralgia. These were coincidental with dietetic and alcoholic excesses. He had not been a hard drinker, but would come under the class of so-called temperate drinkers, and his indulgences were usually associated with excesses in eating. These attacks would pass away in a few days. At times they would last but a few hours, and were never followed by jaundice, constipation, fever, or any general symptoms of any kind whatever. About the 18th of May, 1893, he suffered from one of his old attacks, which was rather more severe than any he had previously experienced. The pain was spasmodic in character, very acute, but subsided in about an hour under the administration of morphia. I did not see him in this attack, nor have I ever seen the patient or prescribed for him during similar attacks. After the attack of pain just described he was apparently in his usual health, but his wife had noticed that he tired easily and complained of fatigue on coming home in the evening from his daily occupation.

On the 19th of May he began to feel quite ill. As he described it to me, he was "sick and achy all over." He had a slight chill; he also developed considerable cough, which was of a short hacking character, almost incessant and attended with considerable pain in the right side and in the epigastrium, pain in the epigastrium being especially marked. On the 20th he consulted me at my office. He still suffered from cough, pain in the right hypochondrium and epigastrium, with severe exacerbations on coughing; still complained of feeling very much prostrated; pains in his bones and mus-

* Professor of the Surgical Diseases of the Genito-Urinary Organs and Syphilology in the Chicago College of Physicians and Surgeons. Attending Surgeon Cook County Hospital, etc.

cles. He presented an expression of distress, and in general looked like a very sick man. His temperature was 102.5°; pulse 110; there was tenderness over the liver; some tenderness over the entire abdomen. The epigastrium seemed to be the focal point of tenderness; the bowels were constipated. Examination revealed a slight bronchitis. He endeavored to repress his hacking cough on account of the pain in the right hypochondrium and epigastrium. I gave him at this time a mercurial cathartic and a capsule containing three grains of phenacetine, 5 grains of salol, and two of quinine, to be repeated every three hours. I instructed the patient not to return to his place of business, but to go home and go to bed, and if he were not feeling better in the morning to send for me. I was not sent for until the afternoon of May 21st. At this time the pain was still marked in the epigastrium; cough quite annoying; there was an obscure sense of fullness in the epigastrium which he referred to his "stomach." He insisted that this fullness was due to somethat was lodged in his stomach, the removal of which would cure him immediately. He stated that he had the same sense of oppression in the epigastrium that he had for a good many years. The temperature was now 103.5°; pulse 120; there was considerable meteorism. On the evening of 21st the temperature as 103°; pulse 108. No antipyretics had been given at this time. On May 22nd meteorism increased; morning temperature 102.4° pulse 120; evening temperature 104°; pulse 130; very moderate use of antipyretics; the symptoms otherwise the same as on the previous day with the exception of the increase in the meteorism.

May 23rd. Morning temperature 103.5°; pulse 120; evening temperature 102°; pulse 118; stopped the antipyretics. The tongue was now dry and brown; the tongue, lips and teeth were covered with sordes; a decided inclination to somnolency; pain in the hypochondrium and epigastric pain not so marked; cough less prominent; still some tenderness in the epigastrium.

May 24. Morning temperature 100°; pulse 110; evening temperature 101°; pulse 120; somnolency increased.

On the 25th, A. M.. temperature was 101°; pulse 114, very intermittent and irregular. Evening temperature 101°; pulse 114; cough somewhat better. Some cerebral excitement. Ice bags were applied to the sides of the neck and to the cranium; no antipyretics were administered. The pulse was so alarming that digitalis was administered. Icterus was now noticed for the first time.

May 26th and 27th. Temperature 99.4°; pulse 108 to 120, and showing the beneficial effect of the digitalis. Pain and tenderness over the hepatic region improved; cough still better, but more or less painful; drowsiness has increased, and the patient has become more or less incoherent.

Until May 24th I considered that I had to deal with a case of typhoid. The early appearance of sordes, the dryness and dark color of the tongue, the peculiar character of the pulse and a sudden diminution in temperature without antipyretics, taken in connection with the localized pain and tenderness over the liver, now led me to suspect the existence either of a primary hepatitis or possibly some hepatic complication modifying the course of an otherwise typical typhoid. At this time I informed the patient's friends that I suspected an acute abscess of the liver, either as a complication or the essential condition present, and suggested that Dr. William E. Quine be called in consultation. My advice as to counsel was followed, and Dr. Quine and myself accordingly met, and after a thorough canvass of the situation we concluded that a positive diagnosis was at that time impracticable, and arranged for a further consultation 48 hours later.

On the evening of the 25th, after careful exploration of the patient's abdomen, I was confident that I could detect a circumscribed induration in the epigastrium, extending down to within an inch and a half of the umbilicus. There was dullness on percussion, and I thought that a reasonably clear outline of the involved area of resistance could be determined by palpation. To me the diagnosis seemed now reasonably clear in spite of the apyrexia, the temperature being at this time slightly sub-normal. On the evening of the 26th, as a preliminary to the coming consultation, I took my instruments to the patient's house prepared to do a laparotomy should I receive the support of counsel. At the request of the

family Dr. Sheldon Leavitt was added to the force of consultants. The final consultation occurred on the morning of the 27th, at which time I expressed my opinion that we had to deal with a circumscribed tumor in the left lobe of the liver with a possible abscess diverticulum of a secondary nature in the right lobe. My consultants agreed as to the probability of pus in the liver, but held that it was in all probability in the form of disseminated abscesses. Counsel agreed to my proposition to use the aspirator. I accordingly aspirated; first over the right lobe, and passing the needle upward and slightly inward toward the median line in the direction of the diaphragm beneath the free border of the rib, pus was struck at the first aspiration. I then aspirated in what appeared to me to be a circumscribed area of induration in the epigastrium, and after several dry taps withdrew a syringe barrelful of what was seemingly sero-purulent material. Much to my discomfiture the eminent gentlemen associated with me in the case asserted that I had aspirated the stomach. As a result of the consultation laparotomy was counseled against. I, however, was not perfectly satisfied and left my instruments at the patient's house. As my consultants had carried the fluid away for examination, I had no immediate prospect of microscopical study of the fluid, but impressed by the urgency of the case, and moreover as my microscope was at my office several miles away, I determined to aspirate again, and during the afternoon of the 27th I called at the patient's house and after the administration of a glass of whiskey and water, colored with several grains of cochineal, I again aspirated in the epigastrium. The appearance and a subsequent microscopical examination in company with my friend Prof. Hektœn, of the fluid which I withdrew, convinced me of the correctness of my conclusions in regard to the case. Accordingly on the morning of the 28th, I called Dr. J. B. Murphy to assist me at the operation, and performed a laparotomy, making a free incision over the area of induration in the epigastrium.

The operation was done under ether anæsthesia with the usual aseptic precautions. On cutting down the median line, and exposing the peritoneum, I found, much to my gratification, that adhesions had occurred between the visceral and parietal peritoneum, thus enabling me to do an extra-peritoneal operation. A large aspirating needle was plunged into the prominent left lobe of the liver which presented at the openi g, and on withdrawing the piston the barrel of the syringe was rapidly filled with sero-purulent fluid. The Paquelin thermo-cautery was now pushed into the liver tissue in the direction of the point of the needle, with the result of evacuating a large quantity of pus. The opening was now enlarged with the finger, the abscess cavity thoroughly explored, and it was found to have involved practically the entire extent of the liver and to present a diverticulum running off into the the right lobe. The pus in this diverticulum was much thicker and presented more of the characters of ordinary pus than from the left lobe, which was comparatively thin. I will state for the benefit of those who may suspect that the gall-bladder was opened, that it was at no time exposed during the operation, nor had I any reason to believe that it communicated with the cavity of the abscess. As an illustration of the depth and extent of the abscess cavity, I will state that a pair of Kocher forceps could be passed both to the right and left of the median line clear to the handles without meeting any obstruction.

The cavity was packed with a liberal quantity of iodoform gauze, and the usual dressing applied. On the second day after the operation, temperature was slightly subnormal, the pulse 118, and of excellent vitality; patient still somnolent, and aroused with difficulty. Icterus still perceptible, although not marked. Third day after the operation, an enormous quantity of bile began to pour from the abdominal wound and saturated the dressings; bile continued to flow from the wound in large quantities for two weeks, when it gradually began to subside, and in a few days had practically disappeared from the discharge. There was a free purulent secretion, but no attempt at repair in the open laparotomy wound for practically three weeks, when it began to heal, and at the end of seven weeks it was perfectly closed. The temperature following the operation fluctuated between the normal and a degree subnormal until toward the close of the case, when it assumed a normal standard and remained normal thereafter.

The tongue, lips and teeth continued

to be covered with sordes, which reformed as fast as it was removed for four weeks after the operation. The tongue was dry and brown constantly during this time. At the end of about four weeks, it began to clear up coincidently with the administration of dilute nitro-hydrochloric acid. For several weeks the patient continued somnolent, and was with difficulty aroused. At the end of three weeks somnolency began to alternate with apparent attacks of mania and insomnia. At times the patient was quite violent, and was with difficulty controlled. For about three weeks after his somnolency began to disappear, his mental condition was very bad, so much so that I suspected some latent cerebral trouble, which had developed under the influence of the constitutional disturbance and toxic disturbance of the brain incidental to hepatic disease. At the end of three weeks, during which time he remained in practically the same condition from day to day, I concluded to experiment a little, and administered Hammond's *cerebrin* in doses of five drops, three times daily. I mention this rather apologetically, and not with the intention of making any claims for the cerebrin. Whether as a coincidence or not, however, within forty-eight hours the patient began to improve, and went on improving steadily thereafter until convalescence was completely established at the end of the eighth week the laparotomy. It would by no means be surprising if the cerebrin-so-called were responsible for the improvement. I imagine that nitro-glycerine in small doses would have had a similar effect. Whatever the physiological effect the cerebrin may have—and any one who like myself has tried it upon himself must acknowledge that it has a physiological effect—is undoubtedly due, in my opinion, to the presence of nitro-glycerine; whether as an accidental or intentional ingredient, is of no moment. I will state that about two weeks after the first operation I explored the liver in all directions on two occasions with aspirating needles of large size with a view of searching for possible purulent collections still remaining in the liver. Dr. D. R. Brower, who saw the case in consultation with me about two weeks after the operation, was inclined to believe that the patient's mental condition was dependent upon pus pockets still remaining in the liver, or upon iodoform poisoning. Thorough aspiration failed to detect pus, and the cessation of the iodoform dressings produced no appreciable effect.

The points of most practical interest in this case are, it seems to me, (1) the probable causation of the abscess by an attack of hepatic colic. (2) The rapidity of formation of pus in the liver. (3) Its location. (4) The early period at which the diagnosis was established. (5) The extensive and speedy destruction of the hepatic tissue. (6) The pronounced and prolonged disturbance of the mental faculties incidental to the toxæmia resulting from hepatic disease. (7) The afebrile course of the case after pus had undoubtedly formed. (8) And most striking of all, the recovery of the so old a patient with so serious an involvement and destruction of hepatic tissue.

It is possible that my patient is not through with his troubles, and I have in mind the possibility of the necessity of a cholectotomy and removal of gall stones later on. At the present time, however, his digestion is perfect; he has an excellent appetite, and is regaining his health as rapidly as one could reasonably expect. A few days since I sent him upon a trip to Mackinaw with the hope of a more speedy restoration to health. It is hardly necessary to call attention to the fact that the favorable result in this case was entirely dependent upon the early diagnosis and operation. Every practical surgeon knows the high mortality attendant upon hepatic abscess, whether operated on or not. My case is an excellent illustration of the rapidity with which the hepatic tissue will break down under the mechanical and toxic influence of pus infection, and shows plainly why, in cases which are not early discovered, surgical measures, however skillful, so frequently fail to relieve the patient. How frequently the diagnosis of hepatic abscess is made only upon the post-mortem table every practicing physician and surgeon is only too painfully aware.

Notwithstanding the disagreement between Dr. Quine and myself as regards the desirability of surgical interference, I can but express my deep obligation to him for the valuable assistance which he gave me in counsel. Our difference of opinion was after all, not upon the question of a suppurative process in the liver,

but of its circumspection and consequent amenability to surgical interference. Frequent daily examinations and careful observation of the case for some days gave me a manifest advantage, which the surgeon does not always have in cases which are primarily of an essential medical character.

I have not attempted to present the literature of hepatic abscess nor to enter into an elaboration of the foregoing case; either would detract from the practicability of the report, and would certainly add nothing to its clinical value.

## DIPHTHERIA.

WM. H. BURR, M. D., WILMINGTON, DEL.

It is certainly very discouraging but yet a fact, that nine-tenths of the stuff which comes under the head of therapeusis in diseased processes, furnished by well meaning practitioners, is the veriest nonsense, thoroughly unscientific and if not productive of harm at least productive of no good. And when anyone for the love of truth undertakes to introduce what he considers a scientific method of treatment, and backs it up with positive practical results, he is simply endured as an unconscious prevaricator.

The above exordium was suggested especially as the result of reading an article on the treatment of Diphtheria.

The treatment of Diphtheria is 1st, a good atomizer, 2nd, peroxide of hydrogen sprayed in the throat every hour in the day time, several times in the night—strength 1-1,1-2,or 1-3; Tr. Fer. Chloride—plenty of it— gtt. x, up to gtt. xxx, every 3 or 4 hours; Quinine from gr. xij to gr. xxv in the 24 hours; plenty of alcohol and all the nourishing food you can get the patient to take. Follow that out and see how many patients you will have to bury, even of the bad cases. Why any one should want to trifle with antipyrine, digitalis, aconite, gesemium, potass. chlorate, etc., I cannot see, they are of no earthly use except to kill patients.

Any one who allows a genuine case of diphtheria to go over 5 hours from time of inception, without diagnosing it and instituting proper treatment, is criminally culpable, whether there is any deposit in the throat or not. The refinements of diagnosis in all diseases that have not their nature written all over them plainly is a thing of the past. The *diphtheritic pulse* has its peculiarity that is not common to any other disease, and the relation of pulse and temperature is also worth studying.

Who that has ever had any experience would think of confounding the diphtheritic pulse and temperature with that found in catarrhal tonsilitis, bronchitis or scarlet fever. The same objection might be made to the miserable temporizing which is followed in the treatment of its companion disease croup. Here again you will find grave and reverend seignieurs fooling along with trifles such as syrup of ipecac, paregoric, alum and molasses, potass. chlorate, etc., etc., waiting for severe symptoms to declare themselves, each minute diminishing the chances by that amount of time of getting a brilliant result from using scientific treatment. What is the treatment of croup? Corrosive sublimate gr. 1-50 to gr. 1-100, every hour, preferably given in gummy solution and kept up for several days; adjuvants—a little ammon carbonatis and ammon. bromidi early in the disease, and quinine later with perhaps a little opium if the corrosive sublimate has a tendency to gripe. Percentage of recoveries ought to be 100.

# THE ERECT POSTURE FOR GYNECOLOGICAL EXAMINATIONS.*

WILLIAM B. DEWEES, A. M., M. D.,† Salina, Kansas.

In accepting the invitation from the Executive Committee of this Association, to present on this occasion a paper on "The Erect Posture for Gynecological Examinations," I wish particularly to impress upon all who honor me by their attention, that my object is rather to elicit than to impart information. To call forth the store of knowledge now latent in the Association ; to ask for the results of your observations, rather than to attempt to add to the knowledge of the members by any contribution of my own. I shall therefore assume the role which has always been my earnest endeavor, namely, to present facts and elicit truth by discussion; also to be sufficiently brief to come within the "ten minute rule."

Digital examination per vaginam with the patient in the erect posture affords me one of the most positive means for diagnosis in gynecology. The horizontal, dorsal, genu-pectoral or knee-chest, semiprone or Sims, and high pelvic or Trendelenberg postures, with the various modifications of the same, are all well urged and abundantly demonstrated by the numerous authors of the present-day literature at our command. But scarce can we find even any mention of the most important posture with which we have to deal, namely, the erect or perpendicular posture. This then is my excuse for presenting this subject for your timely consideration and discussion.

It is a well established fact that respiration, the various movements and attitudes of the body as well as pathological conditions, change the conditions and environments of the viscera. Thus the importance of posturing the patient in making physical examinations in gynecic practice becomes evident. As most of the symptoms of the diseases of the intrapelvic organs are more marked and very many only manifested when the patient is standing, while certain conditions of descent, prolapse or displacement, may entirely disappear or change when the pressure of the superincumbent weight of the abdominal viscera is removed by the patient being placed in the dorsal, semiprone, genu-pectoral, or high-pelvic positions, therefore, the erect posture is of paramount importance as an aid in diagnosis in this field of labor.

In examining a patient lying on her back in the dorsal position, which is the most generally adopted method, and findings ome evidence of displacement it is utterly impossible to accurately determine the degree of the existing displacement without repeating the examination with the patient on her feet. For instance, a patient with a retro-displaced womb, will have the displacement exaggerated in the dorsal posture; whereas a patient with her womb displaced anteriorly will have that displacement lessened if not altogether removed, by the uterus naturally falling backward in both instances. The amount of pressure exercised upon the bladder or the rectum and other posterior structures can be estimated only with any degree of accuracy by having the patient standing. The same holds good in all cases of descent and of prolapsus.

Again a pessary which seems to support a displaced uterus perfectly while the patient is recumbent, may, as is the case in most instances, be found totally inadequate when she rises on her feet. In short, these conditions cannot possibly be certainly determined in any other manner, hence the value and absolute necessity of the erect posture if we would make intelligent examinations and accurate diagnosis.

The examination in this posture is usually made by the patient standing with her back resting against a table or chair placed to the wall or better still, in the writer's experience, by having the patient stand with her back against the wall, and her feet separated about one foot or more. Some examiners prefer the patient to have one foot rest on the rung of a chair. The examiner seated in front and to the

* Read before the Mississippi Valley Medical Association at its Annual Meeting held in Indianapolis, Ind., October 4, 5, and 7, 1893.

† Vice-President Pan-American Medical Congress for Kansas.

Ex-President Golden Belt Medical Society of Kansas.

A Founder and Life-Member International Periodical Congress of Gynecology and Obstetrics.

Member of American and Western Associations of Obstetrics and Gynocology, American Medical Association, American Academy of Medicine, etc., etc.

right of the patient uses the index and middle fingers of his right hand, with the elbow resting on his flexed knee if he so finds convenient. He first examines with the index finger alone, and whenever he finds it essential inserts the middle finger also, which gives him the advantage of at least half an inch further reach. It will be found of additional advantage to place the two fingers with their palmer or flexor surface posteriorly and thus obtain all possibly utility of the fingers in fully exploring the conditions within the pelvis.

In conclusion let me emphasize the advantage and necessity of digital examination in the erect posture more particularly in examinations undertaken for the accurate estimation of

1. Displacements of the uterus.
2. Vesical and Rectal Disorders.
3. Lack of perineal and vaginal support.
4. Ovarian and tubal disorders.
5. Abdominal and pelvic tumors.
6. Differentiation between abdominal tumors and pregnancy.

## REPORT OF THREE MONTHS' SERVICE IN THE JEFFERSON COLLEGE HOSPITAL.*

W. JOSEPH HEARN, M. D., Philadelphia, Pa.

The object of this report is not to include every minor operation, which number over one hundred, but only those which may prove of interest.

One case of fæcal fistula. A young woman, married, two weeks after her first confinement suffered from a strangulated emoral hernia. Her physicians claimed to have reduced the hernia under ether. Subsequently an abscess formed at the femoral ring, was opened, with escape of gas, pus, and some fæcal matter. Four months after she presented herself at the hospital, suffering from an almost constant escape of gas and fæcal matter from a small tortuous sinus below Poupart's ligament. By means of a very small flexible bougie, I was enabled to find the way into the bowel. I cut down on this bougie, following up the sinus until the bowel was reached. As I could feel no spur, I concluded that there was simply a small opening in the bowel. I freshened the edges and closed the wound. Twenty-four hours after symptoms of obstruction of the bowel occurred, with peritonitis, followed by death in three days. A post-mortem examination revealed that, instead of perforation of the bowel with a small opening, a large section of the bowel had been caught in the ring, and at least two-thirds of the circumference had been lost in the slough. The lesson taught me in this case and in other similar cases that I have seen, that the abdomen should be opened in the middle line or outside of the linea alba, in addition to dissecting down through the sinus, in order to find the condition of the bowel and the amount of lost tissue. This was a case for lateral anastomosis.

A second case of abdominal section has the following history: A woman sixty-three years old, was admitted to the ward, suffering with obstruction of the bowels of three weeks' duration. The abdomen was enormously distended, and fœcal vomiting. Incision was made in the middle line below the umbilicus. The intestines were so much distended that it was impossible to locate the seat of obstruction. An incision was made into the small intestines and their contents milked out. This procedure necessarily caused much fæcal matter to be spilt in the abdominal cavity. After reducing the contents of the abdomen the obstruction was easily located. It was a carcinomatous contraction of the middle portion of the transverse colon, with extensive adhesions to the surrounding parts. As it was found impossible to remove the section of bowel involved, an artificial anus was made in the right side. The colon just above the ileo-cæcal valve was attached to the abdominal wall and, as the symptoms

* Read before Philadelphia Academy of Surgery, October 2, 1893.

were urgent, immediately opened. The peritoneum was so tender and brittle, due to inflammatory infiltration, that it was with great difficulty that sutures could be made to hold. The same difficulty was encountered when I attempted to close the opening made in the small intestine. The parts were so thickened that it was almost impossible to invert the intestinal walls for the Lembert sutures. The intestines were returned with great difficulty into the abdominal cavity, which was then thoroughly irrigated. The patient rallied from the shock promptly. Her temperature did not go beyond 101° F. She improved daily, and left the house in four weeks almost as well as she was before the obstruction occurred. The carcinoma had given her but little trouble before the obstruction, not sufficient to cause her to call for medical advice.

A third abdominal section was for ligation of the external iliac artery for an aneurism involving the femoral under and beyond Poupart's ligament and a large portion of the external iliac in the abdominal cavity. The patient was a male, aged forty, and in good health. I determined to do the trans-peritoneal operation. The artery was tied without much difficulty by placing the patient in the Trendelenburg chair and packing the bowels away from the point that I wished to place the ligature, with large pads of antiseptic gauze. The patient made a good recovery, and left the hospital cured. As I shall report this case more fully in another paper, I have purposely omitted much of the technique of this operation. I had two years previously ligated the femoral artery of the same limb.

*Two Cases of Amputation of the Penis for Epithelial Cancer.*—In one case the glands in the left groin were involved, which were removed with much difficulty. The left limb was very œdematous, due to pressure of the enlarged gland on the veins. The difficulty of removal was due to the proximity of those glands to the veins. The patient made a satisfactory recovery.

*Five cases of Hydrocele* were operated upon by the open method. That is, the sacs were incised for about one inch; the edges of the sac caught with hæmostatic forceps to prevent difficulty in getting into the proper cavity. After the cavity is thoroughly dried with antiseptic gauze, pure deliquesced carbolic acid was applied to every part of the serous membrane. Then an iodoform gauze drainage was inserted and left for forty-eight hours. Should the incision be larger than necessary a few catgut sutures can readily be introduced, to partly close the opening. The drainage which this mode of procedure admits of insures absolute success. Anæsthetics are not necessary, as the line of incision can be frozen with chloride of ethyl, and the application of the acid or any other caustic causes no more pain than when injected. Those cases, where the sac is very thick and cannot collapse, or where covered with calcareous plates, are not adapted for this mode of treatment. Only entire or partial excision of the sac will cure that class of cases. The operation of laying open the sac and attaching it to the scrotum, and then packing, I never perform on account of the subsequent deformity.

*Three Cases of Varicocele with Elongated Scrotum.*—I have ceased to perform the operation by the subcutaneous method. Both of these cases were operated upon by the open method, and a section (one inch) of the veins removed. The tied ends are then sutured together with catgut, which insures the shortening of the scrotum. Catgut is also used for ligatures of the veins. The most satisfactory way to reach the veins is to transfix the tissues with knife or scissors, each side being lifted with forceps as the gynecologist approaches the peritoneum. It can be done rapidly and without danger of wounding the vein. With proper antiseptic precautions and properly sterilized catgut the patient will make a more rapid recovery than with the subcutaneous method. I never use drainage, but close the serous membranes with catgut and the skin with silk.

*One Amputation of the Forearm for Epithelioma of the Wrist, which almost encircled the Arm.*—For two years this patient had submitted to the application of caustics from a cancer-curer until the pain became unbearable. The wound healed by first intention, not a drop of pus having been seen. But the pain in the arm never ceased. A multiple neurosis followed the local one after the patient left the hospital, and the patient died eight weeks after the amputation. Alcoholism could not be ascribed as a cause.

Was it the continued use of the caustic applications, which several times caused sloughs, so the patient informed me, that caused exposure of the bones and the tissues between the bones.

*Four Cases of Amputation of the Thigh; one for Sarcoma springing from the Periosteum of the Thigh Bone about the junction of the Upper with the Middle Third.*—The tumor measured twenty-eight inches in circumference and approached the joint so far that an amputation of the hip was thought proper. Wyeth's pins were inserted and the rubber band applied. The flaps were cut for hip amputation, but when the bone was reached it was found in such good condition that the head was not removed. The patient made an excellent recovery and gained much flesh. She was seventy years old and much broken in health when admitted to the hospital. The second case of amputation was for a chronic syphilitic endostitis and necrosis of the lower end of the femur, with an old synovitis of the knee-joint, in a man forty-five years of age, and in an almost exhausted condition. The amputation was made at the junction of the upper and middle third of the thigh. The marrow was soft, almost fluid, and entirely disorganized, and it was not deemed proper to leave it. As the bone seemed healthy I curetted up as far as the trochanter major, and packed with iodoform gauze. The patient suffered very much from shock during and after the operation, but from that time on he improved daily without a single untoward symptom until entire recovery. The third case was that of a man aged thirty-three years, admitted to the hospital suffering from acute gangrene of the left leg. His history was that three weeks previous he had a second attack of an apparent appendicitis under the care of my friend W. L. Coplin. The pain, however, soon subsided in the right iliac region, but severe pain was felt down the left leg. The pain was excruciating, and could scarcely be controlled by large doses of anodyne. Soon after the pain began it was noticed the discoloration of a linear character occurred. It followed the course of the superfical nerves and apparently involved only the skin. Soon gangrene of the entire limb occurred, with great depression of the nervous system. A line of demarcation formed above the knee, and an amputation was advised. The limb was removed at about the middle third of the thigh. The operation was followed by great shock. Very little blood was lost. He rallied for a few days, when gangrene commenced in the right limb. At the same time was noticed that there was no perceptible pulsation in the left radial artery. He sank slowly and died at the end of ten days from an extensive gangrene of the right leg. His previous history was not good. He suffered from chronic alcoholism. He did not suffer from disease of the valves of the heart, but from a fatty heart. An embolus was the apparent cause of the gangrene. The fourth case was that of a boy aged twelve years, who previous to this illness, never was sick. April 1st he commenced having pain in the left knee, and was treated for rheumatism. Soon the swelling involved the knee-joint as well as the whole leg below. His case was then supposed to be one of acute cellulitis, although there was no history of injury or any previous abrasions. He was admitted to the hospial, and several openings were made in the leg and large quantities of pus evacuated. His temperature fell for a few days, but soon arose to 103°, and the boy was slightly delirious. Then it was found that the joint itself was involved. It was opened and a large quantity of puro-sanguinolent fluid escaped. Still the temperature continued above normal, and the boy was still delirious. Other pockets of pus were looked for and opened. Bedsores were threatened and his condition grew worse. At the third operation it was discovered that the boy suffered from epiphysitis of the tibia. Necrosis at the epiphysis had occurred. As the knee-joint was disorganized and the leg from the ankle to the knee was one mass of suppuration, an amputation was advised and accepted. He bore the amputation well, and almost from that day his delirium ceased. The wound healed promptly without suppuration. Very little is said of epiphysitis in the text-books. I think this disease occurs more frequently than we are aware of, though suppuration and necrosis are very rare. I have the history of three other cases, though the symptoms were of a much milder type than the case just mentioned.

*One case of Floating Cartilage of the Knee-joint.*—This I will exhibit to you, and I think you will agree with me that it is

one of the largest. Its dimensions are $1\frac{1}{2}$ x $\frac{3}{4}$ inches.

The man, aged forty-five years, suffered for many years with what he supposed to be rheumatism in his left knee. It had never impeded his locomotion very much. For a long time it must have been too large to impinge itself between the tibia and femur. Its position was on the left lateral aspect of the knee-joint. I cut freely down on it and removed it without difficulty, as it was not attached to any of the fimbriæ of the synovial membrane. Considerable synovial fluid escaped. The synovial membrane was closed with catgut sutures and the skin as usual. No drainage was used. He made a good recovery without anchylosis.

*One Case of Neurectomy of the Infra-orbital Nerve in a Lady of Seventy-three Years, who had Suffered Many Years from Neuralgia.*—Three years previously I had removed the inferior dental nerve for her, with relief for two years. I removed the entire nerve by a trephine opening at the angle of the jaw to the mental foramen. After two years the pain returned in the infra-orbital nerves. This was removed by making a V-shaped notch in the lower border of the orbital bone down to the foramen. By that means I am sure to secure the nerve with all its filaments. Then lifting up the eyeball with a retractor and breaking through the thin floor of the orbit, I was enabled to break off the nerve as far back as its origin. Very little deformity follows the removal of the wedge-shaped bone. It is now five months since the operation, and there has not been any return of pain.

*One Case of Amputation of the Tongue.*—Male, aged seventy-three years. He suffered for many years with papiloma of the tongue, shown in small white plaques. These were partly removed by transfixing with fine needles and tied off. When admitted to the hospital about one-third of the tongue was infiltrated. It was twice its normal thickness, very hard and painful. The glands at the angle of the jaw were also involved. The tongue was transfixed near its tip, and a strong ligature drawn through to give control of it. The patient was placed in a Trendelenburg chair and the head so depressed that no blood ceuld enter the trachea. After etherizing, chloroform was used during the operation. Those who have not used the Trendelenburg chair for operations about the face, nose, and fauces can scarce appreciate its usefulness in preventing suffocation from blood entering the trachea. It prevents the many interruptions to the operator on account of that accident. It does away with the necessity for tracheotomy. With the tongue elevated and pulled strongly forward it controls hemorrhage, as suggested by Heath. Then, with a pair of scissors or a knife, the mucous membrane is divided in a smooth, even, curvalinear line at the junction of the tongue with the floor of the mouth. The object of this line is for the subsequent attachment of the upper portion of the tongue to it. After the tougue was freed as far back as necessary ablation was commenced. With a pair of scissors the tongue was divided by a series of snips until one of the lingual arteries was reached, when it was quickly caught and tied. The pulling forward of the tongue so controlled hemorrhage that but a few drops of blood escaped. Before the next artery is reached another ligature is drawn through the stump, that it too may be under control when the tongue is divided. The stump is then brought forward and sutured to the mucous membrane of the floor of the mouth. By this method there is very little surface exposed for absorption of septic material and the prevention of septic pneumonia greatly enhanced. This patient was fed with a tube attached to the nozzle of the feeding cup, and by that means the food was placed far back in the fauces and did not come in contact with the wound. The enlarged glands were removed, exposing the large vessels of the neck. The patient made a rapid recovery. The stump and floor of the mouth united rapidly, and in six days all the sutures were removed. He suffered much from shock after the operation, but soon rallied. About half of his tongue was removed.

*One Case of Resection of Knee-joint in a Female aged Twenty Years.*—Had suffered for ten years from traumatic synovitis. Her general health good. No history of tuberculosis. When the joint was opened an inflammatory erosion of the entire joint surface was found. The ends of both tibia and femur were sawed off. Temporary fixation of the bone was made with catgut sutures and a plaster splint

applied. Recovery satisfactory. She left the hospital in eight weeks with a good union. Had her to continue to wear a light splint a few weeks longer.

*Four Amputations of the Mammary Gland for Scirrhus.*—In each case the axilla was opened and all its contents removed. Fat was removed, regardless of the fact that in two cases no enlarged glands could be felt. Yet in both cases, when the axilla was opened, minute glands could be distinguished in the fatty material removed. I operate on all cases of carcinoma of the mammæ where the disease has not so far advanced that its removal is impossible. This rule applies to chronic or fibroid scirrhus as well as to the acute variety. I feel it is more beneficent to the patient to let her die of internal cancer than to die of exhaustion due to local ulceration, with all its physical and mental distress. However much confidence the patient may have in her family doctor, who advises her not to have it touched with the surgeon's knife, sooner or later she will disobey his instructions and consult a surgeon, or else fall into the hands of the cancer doctor, with his escharotics. Which of us causes the greatest physical suffering?

*Five Cases of Hare-lip.*—One of the cases simple. Three of the cases with cleft palate, both hard and soft, and one case with double cleft, with intermaxillary bone projecting. In this case I removed the inter-maxillary bone, believing, with Rose, that it interferes with the proper approximation of the lateral maxillary bones. The teeth that form in it are never perfect and are ever useless. I do not use hare-lip pins in approximating the parts, but use silkworm-gut, both at the vermilion border and at the cutaneous surface. I use either catgut or silk sutures for the intervening parts and the mucous membrane. The advantage of the silkworm-gut over pins is that it can be left in longer without cutting or sloughing and supports the parts equally as well. I never operate on a child under one month of age. There is no necessity for it, and union is much less certain.

*Four Cases of Supra-pubic Cystotomy.*—One case of chronic cystitis of ten years' duration, with a small phosphatic calculus. One case of a foreign body in the bladder, part of a soft catheter, and two cases of stone in the bladder. The specimens I now exhibit. The largest stone is from a male patient aged sixty-one years. Occupation, bookkeeper. He suffered for six years with all the symptoms of stone, but his sedentary habits made it endurable until a few months before he was admitted to the hospital. The stone weighs five ounces and is $7\frac{7}{8}$ inches in its greatest circumference. It is smooth, and to that fact is probably due his long tolerance of it. It is probably a uric acid calculus with a phosphatic crust. I was formerly prejudiced in favor of lateral lithotomy, as I had always operated by that method. Now I am convinced that in adults the proper treatment is either supra-pubic cystotomy or lithotripsy, the choice of treatment depending upon the size of the stone or the condition of the bladder and kidneys. I have never crushed a stone in a young child, yet I think it the proper treatment.

---

### Faith in Medicine.

There is virtue in drugs properly administered, but faith cannot be put aside. Faith serves the oculist as well as the physician. A few days ago one of our patients an intelligent gentleman, called to have his lenses changed since they were paining his eyes very much on use. In due time the new lenses came and the old lenses taken out, but by mistake the same old lenses were put back in the frames. He put them on and said they were a great improvement on the old ones. When at home he told his wife everything looked so much clearer with his new lenses, and they were so easy on his eyes. In a short time the mistake was noticed and he was telephoned to come to the office, when it was explained to him how the mistake was made, and the new lenses were put in. The joke was to good; he had to tell his folks. He is now firm in the belief that faith has a wonderfnl effect over the body.

---

In renal colic we are in favor of using atropia in connection with the morphine injection. The atrophine, it is true, counteracts the effects of the morphine to a certain extent, but both are anodynes and it is much safer to use the atropia with such large doses of morphia as are usually required in such cases.

# SOCIETY REPORTS.

## PHILADELPHIA ACADEMY OF SURGERY.

*Meeting October 2, 1893.*

## CARBOLIC ACID USED IN FULL STRENGTH IN SURGERY.

OSCAR H. ALLIS, M. D., PHILADELPHIA.*

Surgeons in early days of antiseptic surgery attributed their success to carbolic acid. As introduced it was employed in a dilute aqueous or oleaginous solution. For a time it was the sole antiseptic. To-day it is mainly used in general surgery as a bath for surgical instruments. Few surgeons will demand a reason for its abandonment. Few have not personally experienced its benumbing effects, and have thus been able to assign the collapse following its employment to something different than loss of blood, shock of operation or anæsthetic.

With such an experience of carbolic acid in its dilute form I confess that I was quite astonished to learn from my friend Dr. B. F. Gardner, of Bloomsburg, that he was in the habit of using the article in its full strength upon extensive cut surfaces, and that, too, with the happiest results. As this article owes its entire value to Dr. Gardner, I will give in detail his method.

When Lister introduced his paste Dr. Gardner used it quite extensively. After an application to quite an extensive wound surface he was surprised to find it turn white, and that he had used pure carbolic acid. He therefore immediately washed the surface and dressed the wound, keeping it open until oozing had ceased. The case did so well that it inaugurated with him a line of treatment that he has exensively employed. As a typical application let me take an amputation of the female breast. After its removal and the ligation of the bleeding vessels carbolic acid crystals, dissolved in sufficient water for solution, are applied with a sponge to all parts of the cut surface. Immediately upon the application of the acid the tissues turn white, which is a guarantee of its thorough action. The wound surface is then washed with water previously sterilized by boiling, and then approximated with provisions for drainage. This is especially necessary, as for twenty-four hours the oozing must find ready exit. During the first few days there is a slight local hyperemia along the borders of approximation, but this declines without crisis.

Dr. Gardner claims for carbolic acid applied in officinal strength :

1. That no systemic absorption attends its use, and hence no danger, no shock.

2. That it is a local anæsthetic. Hence there is not as much pain after the operation.

3. That it is in a measure a hæmostatic, acting especially upon the capillary vessels.

I have taken the removal of the mamma only as an illustrative case. In all operations outside of the pleuritic and abdominal cavities, such as amputations and resections, Dr. Gardner resorts to it.

In hydrocele he lays open the sac freely, then applies carbolic acid to the tunica vaginalis, and concludes with packing or drainage. The operation is not followed by excess of any kind, and recovery is prompt. He has used it in gunshot wounds of the knee and ankle. If he gets such a case after suppuration has set in he freely opens the joint, applies the carbolic acid to every part, washes out all excess freely, secures ample drainage with fixation, and confidently awaits the result. Anchylosis may follow, but this will depend on the extent of the injury, the delay in treatment, the conduct of the patient. Dr. Gardner has used bichloride of mercury, hydrogen peroxide, iodoform, etc.; none of them has answered the claims made for them; all have disappointed him, but pure carbolic acid *never*.

I have said that Dr. Gardner does not use this upon serous membranes *i. e.*" within the abdomen. I must modify this

* Surgeon to the Presbyterian Hospital.

statement. In a case of strangulated hernia, in which he found patches of sphacelus—not deep, but threatening—he cautiously applied the pure acid and returned the gut. Fortunately the strangulation had been arrested by operation in time to save the gut. Nothing eventful in the subsequent history, which was speedy.

I do not know Dr. Gardner's theory of the actions of this powerful drug, and shall attempt no explanation. The turning of the wound surface white is due probably to the coagulation of the albumin of the tissues and fluids of the wound surface, and not that the acid has a necrotic effect. That it does not produce a true destruction of tissue may be inferred that after a large breast or thigh amputation he will have primary union and no suppuration. In its use in hydrocele a half drachm or more is injected into the tunica vaginalis, and resolution without suppuration ensues. It is possible that by its action upon the wound surface an action similar to that obtained by heat may be produced, and thus facilitate repair.

I will conclude this article by briefly stating my experience with it.

On entering the wards of the Presbyterian Hospital I found that one of my amputations of the thigh had not done well, and looking at the stump found it swollen and of an angry threatening character. The seam of approximation was perfect. I therefore removed all the sutures, and separating the flaps found them almost in a stage of gangrene. Taking carbolic acid, pure, I applied it freely, pressing it into the tissues with the sponge applicator, removed the excess, and, packing the space between the flaps renewed the dressing. This was done without anæsthetic and without apparent pain. The exposed surfaces soon began to granulate, when they were approximated and recovery soon followed. I have also frequently applied it upon a carrier with cotton to sinuses and after curetting glands.

DISCUSSION.

Dr. H. R. Wharton: I would like to ask if Dr. Allis has seen carbolic acid poisoning from the use of the agent in this way. I have never seen much trouble from the use of carbolic acid except in children. At the Children's Hospital I have seen two or three cases where its use has produced a marked constitutional effect. In one instance where a large nævus was dressed with carbolic acid application there was a dark-colored urine and other symptoms of poisoning.

Dr. William J. Taylor: I think the application of pure carbolic acid to a fresh, clean surface, such as is left after the removal of the breast, is totally unnecessary. If you have a thoroughly clear skin, clean instruments, ligatures, and hands, you will have primary union. If such a fresh surface is smeared with carbolic acid there will be a large amount of oozing. My experience with a few cases where strong carbolic acid solutions were used a number of years ago was that healing was much retarded.

As an application to suppurating surfaces such as Dr. Allis speaks of, and where you wish a cauterizing and disinfecting action, I consider carbolic acid one of the best agents that we have, and use it frequently.

Dr. W. Joseph Hearn: If carbolic acid is applied to a raw surface, otherwise healthy, one would expect to have a certain amount of necrosis of the tissues. Some cells will be destroyed, and afford a soil for the propagation of germs.

Dr. Richard H. Harte: Dr. Levis was in the habit of using carbolic acid for its cautery effect. I remember several cases where he used it freely, producing large sloughs over the posterior surface of the thigh.

Dr. Allis: In regard to poisoning Dr. Gardner claims immunity from poisoning from the fact that the application scars the whole surface and closes the small vessels, and nothing is taken into the system. Dilute solutions are rapidly taken up. In one case where I operated on two herniæ in the same individual there was a good deal of collapse following the use of a dilute solution of carbolic acid. I am not prepared to say whether it has a necrotic action or not. I do not understand how Dr. Gardner gets primary union using it as he does if it has such an action.

I think that Dr. Gardner probably began its use with the idea that there might be left after amputation of the breast some cells which it would destroy. I do not bring this forward thinking that anyone will be led to use it in these cases, but there is a big lesson in this use of carbolic acid. There are places where it

is valuable, for instance, in deep sinuses and pus tracts. I have injected it into a psoas abscess so that it would run out—probably eight ounces—without the slightest constitutional effect.

I can subscribe to what Dr. Harte says. Care must be taken that the carbolic acid does not come in contact with the skin. If it touches the skin it will blister it, but when applied to a raw surface it does not have the effect which we should expect. In a few cases where it had been injected into the tunica vaginalis the patients have almost died, but in a large majority of cases carbolic acid pure in hydrocele effects a happy cure and without suppuration. Hence without necrotic action.

In collecting some cases of accidents in the treatment of hydrocele such cases were reported to me.

As to whether or not the application in recent surgery is necessary or advantageous I leave that for individual opinion. I have seen bichloride solution do as much mischief as carbolic acid probably could do in preventing primary union.

Dr. L. W. Steinbach: In speaking of the use of carbolic acid Dr. Levis has been referred to. A number of years ago I had the pleasure of assisting Dr. Levis in the removal of an ovarian cyst in private practice. At that time the spray was used. The assistant who had charge of the spray put the carbolic acid in the bottle and the water on top of it without mixing the two, so that a spray of pure carbolic acid was delivered into the wound and on to the operator's hands. The doctor's hands became so benumbed that he was unable to introduce the stitches. The woman, however, made an excellent recovery.

Of course every one knows the good success of Dr. Levis in the treatment of hydrocele with carbolic acid. He was careful that none got into the connective tissue or on the scrotum. I never saw an accident in any of his numerous cases.

Dr. W. Joseph Hearn read a "Report of Three Months' Service in the Jefferson College Hospital." See page (855).

DISCUSSION.

Dr. O. H. Allis: I would ask Dr. Hearn if he has seen any sloughing in the cases of hydrocele where he has used carbolic acid?

Dr. William J. Taylor: I had the pleasure of seeing Dr. Hearn operate in the case of intestinal obstruction referred to. I never had seen such distension of the intestine. The small intestines were larger than the average colon, and the tissues were so soft that the sutures tore out. It is simply a miracle that the woman survived.

Dr. W. W. Keen: It is impossible to refer in detail to the five series of cases which Dr. Hearn has reported from a service of eight or ten weeks, but there are two points to which I wish to call attention. One is the use of the Trendelenburg posture in all cases of operation about the mouth and nose. A preliminary tracheotomy has often been advised and has been done in these cases. Of course, tracheotomy is not one of the most serious operations, but it does add to the complications. As Dr. Hearn has said, I believe that the use of this position will practically do away with preliminary tracheotomy in most cases, and always if the tracheotomy be for the purpose of preventing blood entering the larynx and lungs.

I notice also with much pleasure that Dr. Hearn has drawn attention to the importance of uniting mucous membrane after removal of the tongue. I think that this is of great importance in order to avoid as far as possible any opportunity for septic infection. In removal of the lower jaw in a number of cases I have endeavored to unite the mucous membrane so as to cover in the raw surface entirely. If we do that there is no opportunity for infection of the system.

These two points in the surgery of the mouth are of great importance, and it is only in late years that I have recognized their importance; but experience has taught me the immense benefit to be derived from these procedures.

Dr. Hearn: In reply to Dr. Allis, I would state that I have never seen sloughing from the use of pure carbolic acid. In one case, where the surgeon introduced a dilute solution, sloughing followed, and a few days later the testicle could be seen. Where I have used pure carbolic acid I have never seen any accident. I have always injected it until I began this procedure of opening the sac. I have never seen the latter operation fail. The opening permits thorough drainage and is sure to succeed.

# THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS

Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D., Editor.

RODERIC C. PENFIELD, Publisher.

PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, DECEMBER 2, 1893.

## EDITORIAL.

### THE REAL VERSUS THE IDEAL IN THE PRACTICE OF MEDICINE.

It is said of the late Sir Andrew Clark, whose death the entire profession deplores, that he frequently asserted his intention to "die in harness," and the impression prevails that he died practically from overwork. His devotion to his profession was intense; the performance of his duties most conscienscious; his success remarkable; his popularity amazing. It is said his common-sense was equal to his skill, and he must have known that he was doing too much for safety.

It might be a question of abstract ethics whether or not this purpose was, in his case, justifiable, but the vast majority of physicians the world over, who have reached the same period of life, have no choice but to "die in harness." The *London Spectator*, anent this subject, says: "Of all the social changes of our time, this one—the increasing reluctance of professional and business men to retire from active work—is probably the most marked. The old idea that a man at sixty ought to be content with his gains and stop work has, except as a basis for official schemes of compulsory retirement, utterly died away.

Three distinct changes have operated together to make a grand alteration both in opinion and in practice. In the first place, the health of the cultivated has improved, especially in the later years of life, so much, that work can be done, and done well, by men of seventy, which, only half a century ago, men of sixty would have hesitated to undertake. The judgment is as clear, the insight as keen, and the power of absorbing new facts nearly as great as ever. The cultivated are old, in the ancient sense, at seventy-five, and feeble at eighty, that is half a generation at least later than used to be the case. In the second place, the idea of the duty of "making one's soul" in idleness has died out of moral teaching, and the pious think that they can reflect and pray and repent all the better because they are not consumed by ennui or tormented by the rather inane chat which is apt to be-

come the occupation of the 'retired.' And in the third, it is far more difficult than it was to be careless of professional gains. Business men occasionally make more than was at all frequent in the forties, but professional men do not, and the decline in the rate of interest obtainable for savings has cut their fortunes in two. They cannot get 3 per cent. clear where in 1840 they could get 5 per cent., or even, with courage and a little luck a secure 6 per cent."

These social conditions unfailingly react on younger men. Opportunities for success early in life are less often presented; prospects of securing a respectable living are diminished; considerations of marriage and family must be postponed until later in life—although the physical development of the individual is not at all modified. In general, the younger generation has to wait longer for all things or be regarded as presumptuous for aspiring to a better estate.

These conditions never enter into the calculations of the youth who are flocking to the medical schools, most of whom would be at a loss for a sufficient reason if asked the motive impelling them to the study of medicine. According to the *British Medical Journal*, "there are two answers to the inquiry which are commonly suggested. The practical one suggests that, as in the great majority of cases it is imperative for the candidate to choose some method of earning a livelihood, he may possibly succeed better as a doctor than in anything else. The other, which can never be out of date, and of which the tradition renews its vitality in the introductory addresses at the opening of the medical schools, has for its basis the devotion to humanity and the enthusiasm of doing good. Probably only a very small proportion indeed of those who enter the medical schools will do so simply as an act of self-sacrifice on the altar of humanity in the concrete, or of science in the abstract, and we may, at any rate, confine our attention and address our remarks to those why simply seek a means of livelihood in an honorable and interesting profession. There is a legend in an ancient Buddhist manuscript of the early days of the physician of the Gotama Buddha, whose name was Jiwaka, which puts the case for the aspirant for medical honors very aptly for our present purpose. It having become necessary for the youthful Jiwaka to select a profession, "he considered the character of the eighteen sciences and the sixty-four arts, and determined that he would study the art of medicine that he might be called doctor, be respected, and attain to eminence." If we assume that the student selects our profession in order that he may "be called doctor, be respected, and rise to eminence," we shall probably have a very fair and a very proper answer to the question, what impels so many to enter the portals of medicine?

---

GEIGEL says that more illegitimate than legitimate children suffer and die from diseases of the alimentary canal, but that more legitimate children die of diseases of the respiratory tract. Bad food and irregularity of feeding accounts for the former, and coddling and keeping them in doors—in other words, over-care—accounts for the latter. The more intelligent class of people are remedying this defect to a great extent as well as the reform in dress.—*Ex.*

---

SICKNESS at stomach with coffee ground vomit in either acute disease or low forms of fever is a grave symptom. But a careful inquiry should be made of nose bleed or of blood found on the handkerchief after blowing the nose, especially in the mornings. With a history of blood from the nose, the chances are it came from the posterior nares and passed down the œsophagus into the stomach during sleep.—*Ex.*

---

In case of poisoning by any of the preparations of opium, atropine is the antidote. It is safe to inject hypodermatically from one-sixtieth to one-thirtieth of a grain at one dose in the beinning.

# BACTERIOLOGICAL NOTES.

## THE EXISTENCE OF PATHOGENIC BACTERIA IN THE UPPER AIR PASSAGES OF MAN AND HEALTHY ANIMALS.

In 1880, Sternberg demonstrated the presence of bacteria in the saliva of healthy men, that were capable of producing a rapidly fatal septicæmia in rabbits and which have since been found to be the cause of pneumonia in man. Almost simultaneously this organism was discovered by Pasteur, whose publications of the discovery preceded Sternberg's by a few months. In 1891, Smith (*Cause and Prevention of Swine Plague, Department of Agriculture,* p. 107) was led to an examination of the secretions from the mouth and posterior nares of apparently healthy swine for the purpose of determining whether or not bacteria could be found in the floor of the upper air passages that were identical with or similar to those found apparently as the etiological factor in the diseased lungs of animals suffering from swine plague. The result was positive as bacteria not distinguishable from those of virulent swine plague were found in the nose, mouth and larynx of a certain number of healthy swine. This discovery was of much importance in explaining the source of swine plague bacteria in the isolated or sporadic cases of the disease where an infection from without could not be explained on account of the nature of these bacteria which are rapidly destroyed by drying, or when placed in water or under other conditions unfavorable for their development. In an appendix to this report Moore recorded the results of a few preliminary examinations of the secretions from the upper air passages of certain other domesticated animals which were made for the purpose of determining the extent of the distribution of these bacteria. In these investigations he found in the mucosa of the upper air passages of a certain per cent. of such animals as cattle, cats and dogs, bacteria which could not be differentiated from the swine plague germ.

Fiocca (*Centralblatt f. Bakteriologie u. Parasitenkunde*, XI 1892, p.406), reports the discovery of a pathogenic bacillus in the saliva of cats and dogs which resembled the bacillus of rabbit septicæmia, but of only one-half its size. He believed it to be the germ of *la grippe*. In the light of more recent investigations it is presumable that this germ belongs to the swine plague group of bacteria.

Moore has recently (Bulletin No. 3, Bureau of Annual Industry, Department of Agriculture, 1893, p. 58), published the results of more extended observations in which he has found that pathogenic bacteria which for the greater part belong to the swine plague or pneumonia group of organisms, are present apparently in their normal habitat in the upper air passages of 48 per cent. of pigs, 80 per cent. of cattle, 50 per cent. of sheep, 16 per cent. of horses, 90 per cent. of cats, and nearly 30 per cent. of dogs. The secretions from the air passages of rabbits, guinea pigs, fowls, turtles and frogs were also examined, but with negative results. This result is of considerable interest as there are several cases reported of disease in rabbits, fowls and guinea pigs, in which bacteria not distinguishable from the swine plague germ, have been found associated apparently as the causal factor in the lesions produced.

Another and most interesting feature of their observations is the very large percentage of cats that are normally infected while these animals are insusceptible to these bacteria when inoculated with large quantities of a pure culture. It should be borne in mind that the bacteria resemble very closely the pneumonia germ, (*Micrococcus lanciolatus*) in man, in their cultural character and in their effect upon the smaller experimental animals.

In addition to the pathogenic bacteria other forms were isolated which at first were destructive to mice or rabbits but later exhibited no pathogenic properties whatever. The method employed was the subcutaneous inoculation of rabbits with the mucus taken, with great precautions against infection from without, from the mucosa of living or freshly killed animals. In the great majority of cases the mucus was taken from the freshly killed animal.

The practical importance of the presence of bacteria in the upper air passages of man and the lower animals is not clearly demonstrated, but they serve to explain to a certain degree the source of the germs in isolated cares of pneumonia and the occasional presence of toxicogenic bacteria in the diseased organs of animals. The conditions under which these forms of bacteria become destructive to their host is not yet determined, and all that appears to be known is that they exist in the secretions covering the mucosa of certain animals and man, and that these species frequently perish with lesions containing bacteria which can not be differentiated from the germs found on the normal mucous membrane.

The various observations that have been made on the pathogenic bacteria which normally inhabit these mucosa are of much interest in pointing out the possible relations that may exist between these bacteria found in man and animals and the possibility of infection one from the other. Thus far the habitat of these pathogenic bacteria outside of the animal body has not been found although certain toxicogenic bacteria have been found in the soil and in water.

## THE WILLIAM F. JENKS MEMORIAL PRIZE.

The third triennial prize, of five hundred dollars, under the deed of trust of Mrs. William F. Jenks, will be awarded to the author of the best essay on "Infant Mortality During Labor, and its Prevention."

The conditions annexed by the founder of this prize are, that the "prize or award must always be for some subject connected with Obstetrics, or the Diseases of Women, or the Diseases of Children;" and that "the Trustees, under this deed for the time being, can, in their discretion, publish the successful essay, or any paper written upon any subject for which they may offer a reward, provided the income in their hands may, in their judgment, be sufficient for that purpose, and the essay or paper be considered by them worthy of publication. If published, the distribution of said essay shall be entirely under the control of said trustees. In case they do not publish the said essay or paper, it shall be the property of the College of Physicians of Philadelphia."

The prize is open for competition to the whole world, but the essay must be the production of a single person.

The essay, which must be written in the English language, or if in a foreign language, accompanied by an English translation, should be sent to the College of Physicians of Philadelphia, Pennsylvania, U. S. A., before January 1, 1895, addressed to Horace Y. Evans, M. D., Chairman of the William F. Jenks Prize Committee.

Each essay must be typewritten, distinguished by a motto, and accompanied by a sealed envelope bearing the same motto and containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay.

The Committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents, within one year.

The Committee reserves the right not to make an award if no essay submitted is considered worthy of the prize.

JAMES V. INGHAM,
*Secretary of the Trustees.*

### Arsenic Internally in Cancer.

Dr. Lassar (*Arch. de Ginecol. Pediat.*) was consulted by a patient who presented three cancerous ulcerations of the face, nose, forehead and chin. Histological examination confirmed the diagnosis, and, on account of operative interference being contra-indicated, he prescribed arsenic internally, in the following formula:

Fowler's solution, } equal parts.
Peppermint water, }
Five drops of this mixture three times a day.

At the end of five or six weeks the nasal lesions had healed and the others were undergoing cicatrization. This observation was incomplete, as the patient disappeared from view; but in another case he was able to follow the process of healing, step by step, to complete recovery. On account of these successes he tried it in cases less advanced, and the results obtained were the same in three cases, which presented cancerous ulcers and where the diagnosis was certain.

## MALIGNANT LYMPHOMA.

Dr. F. Fischer reports 2 cases which he observed in the clinic at Strasbourg. The first occured in a man aged 34, and presented the oft described peculiarity of a recurrent pyrexia. The author found in this patient, during two febrile attacks, that the blood contained staphylococci, while it was free from such micro-organisms during the absence of fever.

This was observed at an earlier date in analagous cases by Mayocchi and Picchini and also by Hewelke. The author regards this questionable fever as one to be classed under the head of infection produced by staphylococci, and states that since it was impossible to locate any point of infection during life or at the autopsy, the mouth and alimentary canal must have served as the means of entrance for these micro-organisms.

According to this observation the fever in Malignant Lymphoma, must be regarded as secondary, and not as Ebstein and Pel expressed themselves, namely, that it was a peculiar increase in the infectious form of this disease. The author regards the period of apyrexia as one of immunity after the invasion of the cocci.

Case second. A boy aged 6, who died of tubercular disease of the lungs, having previously suffered of malignant lymphoma. This combination has been frequently shown by other authors.

Though others have considered a direct and near connection between these diseases, the author still declares himself negatively on this point, referring to some experiments on the lower animals, in which the enlarged cervical glands were free from tuberculous matter, even though the lungs and intestines were invaded. Based upon this, F. feels that lymphoma, sarcoma and tuberculosis may run each their separate courses independently in the one patient at the same time.—*Centralb f. Chirurg. No 39.* W.

### Trephining for Subdural Hemorrhage.

O. Riegnor reports a case of a child, aged 7½ years, who fell out of a first-story window upon the head; he became unconscious and remained so when admitted to the hospital. During the next 4 days, there were clonic spasms of the extremities; choked optic disc; and slowing of pulse, while consciousness began to return slowly, the patient, however, being unable to express himself in words. A diagnosis was made of an intra-cranial hemorrhage of the meningeal artery. A fissure of about 2 mm. in breadth could be felt in the left temporal region, and it was decided that trephining should be performed at that point. This operation disclosed the presence of a subdural hemorrhage, also that a greater portion of the brain had sustained grave injury. Careful removal of all blood clots and injured brain tissue, tamponing and dressing constituted the operation and resulted in a thorough normal recovery. One and a half years later the author was enabled to perform an osteoplastic operation to cover the defect in the skull, which had in the meantime became larger instead of smaller. This was also followed by good results. The fear that the boy might remain speechless, due to the destruction of brain tissue was not realized, although some time elapsed before he recovered full command of speech. The motor centres of the extremities soon regained their functions after the first operation.—*Deutsche Med. Wochen. 93.* W.

### A Case of Poisoning by Lysol: Tracheotomy.

Dr. Roede reports (*Deutsche Zeitsch. f. Chirurg*), a case of a child of 10 months, who had been given by mistake a spoonful of pure Lysol instead of Cod Liver oil. Symptoms of laryngeal stenosis at once set in making it imperative to perform tracheotomy as a means of relief. In spite of all active treatment symptoms of excitation, convulsions followed by stupor, compressible frequent pulse, set in until death closed the scene.

There was no grey swelling nor marked changes in the kidneys. The symptoms of poisoning were similar to those of carbolic acid, except the changes in the urine. The author considered the report of this case a necessity since it serves as a warning against the present theory of harmlessness of the drug. W.

# THERAPEUTIC HINTS FROM FOREIGN JOURNALS.

IN CHARGE OF THE TRANSLATOR, F. H. PRITCHARD, M. D.

## ITCHING AFTER ERUPTIVE DISEASES.

Dr. Kein (*Medicinische Neuigkeiten* No. 42, 1893) from an extensive series of experiments in polyclinical and private practice, finds that lanolin, with addition of 60 per cent. water, is one of the best means of alleviating the itching of scarlet fever, measles, etc. The formula is as follows :

℞ Anhydrous Lanoline ..... 50 gms. (℥jss).
Vaseline..... 20 gms. (℥v).
Destilled Water..... 25 gms. (℥vj).
Rub in every three hours.

The large quantity of water contained in the salve causes a rapid evaporation of water held in suspension, on the surface of the patient's body, with consequent cooling of the skin. Thus, the capillary hyperemia of the skin is diminished and the itching favorably affected. It is absolutely unirritable, rapidly absorbed, and it is to be used in every stage of the exanthems.

## MIGRAINE.

Dr. Freudenberg (*Medicinische Neuigkeiten* No. 42, 1893), of Dresden, has, for the last few years, employed the following formula in migraine, with good results, and he heartily recommends its trial :

℞ Muriate of Morphine..... 1 cgm. (gr. 15).
Salicylote of Soda.....
Phenacetine .....ana ..... 25 cgms. (grs. iv).
Divide into ten capsules.
One to two capsules at a time, until relief.

## PRURIGINOUS AFFECTIONS OF THE SKIN.

Dr. Bronson (*La Sémaine Medicale* No. 63, 1893) recommends the following formula in the treatment of itching skin diseases :

℞ Carbolic Acid Crystals..... 4-8 gms. (℥j-ij).
Solution of Caustic Potash. 5 per cent. 4 gms. (℥j).
Linseed Oil..... 30 gms. (℥j).
Essense of Bergamot..... gtts. ij.
For external use.

Dr. Bartholow (*La Semaine Medicale* No. 63, 1893), speaks highly of the following formula in pruritus of the vulva :

℞ Sublimate..... 40 cgms. (grs. vij).
Alum..... 8 gms. (℥ij).
Starch ..... 40 gms. (℥i ¼).
Water..... 1 qt.
For external use.

## TREATMENT OF DIPHTHERIA.

Dr. A. Blanchini (*La Semaine Medicale* No. 63, 1893) has obtained excellent results in the treatment of diphtheritic angina in children, by the application of a compress of absorbent cotton, wet in a 5 per cent. solution of carbolic acid, and applied around the neck. They are to be continued until the temperature of the little patient becomes normal, which soon follows. In consequence of the greater sensitiveness of children to carbolic acid it is well to watch the urine in order to interrupt treatment as soon as the slightest signs of carbolic acid poisoning are observed.

Besides these compresses he also gives, internally, the following formula :

℞ Liquid Perchloride of Iron.... 2 gms. (gtts. xxx).
Orange Flower Water ..... 200 gms. (℥vjss).
Simple Syrup..... 20 gms. (℥v).
A soupspoonful every hour.

An Italian physician, Dr. Muller, of Belluno, recommends petroleum, in diphtheria. It has been recently praised in follicular angina. He commences by cleansing the throat with a solution of salicylic acid, and, after having detached as much of the false membranes as possible, he applies pure petroleum, locally, every two hours.

## BEE STINGS.

Dr. Pedkow (*Muenchener Medicinische Wochenschrift* No. 43, 1893), recommends in stings from bees and other insects rubbing in a few drops of a saturated solution of naphthaline, in vaseline. It is to be repeated every three to four hours.

## BROMOFORM IN WHOOPING COUGH.

Dr. Burton (*Muenchener Medicinische Wochenschrift* No. 43, 1893) like Stepp, has employed bromoform in whooping-cough, with very good results. He treated thirty children varying in age from three months to eight years. From the second day, the attacks became less frequent and violent, together with the epistaxis and other hemorrhages, the expectoration was rendered easier and the bronchitis was cured. Only one child, who suffered from capillary bronchitis, died. The dose was one to three dgms. (one and a half to five drops) in children and from a gram, (fifteen drops) to a gram and a half (twenty-two

MALIGNANT LYMPHOMA.

drops) for adults. It was prescribed in a solution of gum tragacanth, syrup and water. Stepp ordered the remedy in doses of five to twenty drops, per diem, and, in the following formula :

℞ Bromoform..... gtts. x.
Alcohol..... 3-5 gms. (gtts. xlv-ʒjss).
Water..... 100 gms. (ʒiijss).
Syrup..... 10 gms. (ʒijss).

A tablespoonful every hour.

TREATMENT OF ERYSIPELAS.

Dr. H. Koester (*Wiener Medizinische Presse*, No. 43, 1893) describes a method of treating erysipelas which he has used in fifty cases during the last year, in the hospital at Gothenburg, Sweden. It consists in covering the affected portions and the surrounding skin with a thick layer of white vaseline, by means of a brush. A piece of linen is applied over the whole, in case of the face holes being cut for the mouth and eyes, and this fixed by means of a gauze bandage, with slight pressure. Twice a day new vaseline is painted on and the soaked piece of linen reapplied. The results were extremely good and from comparison with treatment with iodine, ichthyol, sublimate and lanoline it gave fully as good results. The fever fell, in most cases, within two or three days; the sensation of pain and tension in the affected parts soon became less and recurrences were not observed more frequently than with other methods. In some cases the results were astonishing. Patients that one evening came under treatment with a fever of 40° C, were, the next morning, free from fever and the disease had ceased to extend. Though the result was not so striking in all cases the disease was generally limited to the areas first affected. This method is not only indicated in erysipelatous processes upon the skin but it may also be used in case the scalp is attacked. Here it can be employed without cutting the hair. The advantages are its simplicity, its lack of danger, and, for the patient, it is more agreeable than pencilling with iodine, ichthyol or sublimate-collodion, which often cause burning pains and quite severe symptoms of irritation.

CREASOTE IN LATENT TUBERCULOSIS.

Dr. Blanchard (*La Semaine Mèdicale*, No. 83, 1893) has obtained in latent tuberculosis, with creasote, not only more or less improvement but also complete and rapid cure. It is well known that creasote exercises a favorable action upon pulmonary tuberculosis; in general, the earlier given the more pronounced the effect. It is often prescribed in the initial stage of confirmed phthisis but neglected in the latent stage where a diagnosis can only be presumed. He has employed it in seventeen cases and although they did not present pronounced signs of pulmonary localization, symptoms were observed which pointed to a developing tuberculosis: a cough dry or with muco-purulent expectoration, dyspnœa, progressive emaciation, general weakness, night sweats, diarrhœa. Besides the diagnosis was also strengthened by the existence of hereditary antecedents and a history of preceding grippe. Influenza is, as is well known, a frequent cause of pulmonary tuberculosis. Finally, there were three patients who were infected from contact with other members of their family who were undoubtedly tuberculous.

In all these cases, creasote produced a rapid and complete recovery. He administered it, in all cases, by the rectum. Each rectal injection contained 250 grams (8 ounces) of tepid water, the yelk of one egg, and an increasing quantity of creasoted oil of sweet almonds, 1:30. He began with four drops of creasote and increased the dose up to thirty, and even forty drops, per diem. If the amount surpassed one gram (fifteen drops) it was given in two or three injections. The patients took no other remedy. From his experience he concludes as follows:

1. Pulmonary tuberculosis may be cured. This should be made known to the patients and their families in order that they may have the benefit of early treatment and understand the gravity of the affection, from the beginning.

2. Creasote is a very active agent in pulmonary tuberculosis. Its influence is especially manifest in latent tuberculosis, where it may be used to confirm the diagnosis and bring about a rapid and lasting cure.

3. It is very important to diagnose as early as possible in latent tuberculosis in order that the patient may have the advantage of early treatment.

Creasote, given by the rectum, in sufficient doses, will produce a rapid and com-

plete cure of insidious bronchitis of grippal origin which he maintains is only a developing tuberculosis. If used with prudence, it has no inconveniences even in case of error in diagnosis.

LARGE DOSES OF OLIVE OIL IN LEAD COLIC.

Dr. Combemale (*Le Progres Mèdicale* No. 42, 1893) by a single large dose of olive oil of 200 grams, (seven ounces,) with the addition of menthol or cocaine in order that it be tolerated, has obtained favorable results, in lead colic. The oil is deobstruent and sedative which action is by no means as easily obtained with other therapeutic measures. In doses of an ounce and a half per diem, he has obtained a cessation of the nervous phenomena in chronic lead poisoning.

A NEW TREATMENT OF HYDROCELE.

Dr. J. Neumann (*Weiner Medizinische Presse* No. 45, 1893) describes a method of treating hydrocele which he has employed successfully in six cases. After careful disinfection a trocar is introduced into the tumor. While the serous fluid is flowing out it is pushed up still higher, left in the sac and a slightly compressing bandage applied. This is allowed to lie undisturbed for about two days. In all of his cases there followed adhesions of the two layers of the sac without suppuration or inflammation. The time of treatment lasted from seven to nine days. After removal of the canula the after treatment consisted only of cooling applications as of lead water to the scrotal skin which will still be reddened and somewhat swollen. The advantages of this method are its simplicity the shorter duration of treatment, less pain and assurance against subsequent inflammation. He explains its action by the alteration in in the efflux of the fluid, and the pressure of the canula which easily gives rise to an emigration of leucocytes which, decomposing, give rise to a fibrinogenous ferment which induces coagulation in the serum consequently produced. The slight compression of the bandage and the draining away of the surplus serum lead to adhesion of the layers of the serous membrane so that adhesion without inflammation occurs. Strict asepsis is necessary.

POMEGRANATE BARK IN DYSENTERY.

Dr. Graeser (*Deutsche Medicinische Wochenschrift* No. 90, 1893) speaks highly of the value of pomegranate root bark, in dysentery. His patients were chiefly the troops of the Dutch Colonial Army. He employed it in a macerated infusion of this and simaruba bark in wine, every two hours a teaspoonful of the maceration. This preparation is made by macerating 10–15 grams (two to four ounces) of the pomegranate root and simaruba bark in a bottle, 750 gms., of French red wine for 24 hours. As food, rice with boiled chicken, raw ham, barley soup, eggs, and potato porridge were administered. For the torturing and intolerable thirst he gave small pieces of ice with, here and there, a few drops of brandy. In all he employed this treatment in thirty cases of pronounced dysentery which were partly acute and partly chronic. They all improved or recovered completely. Only one old soldier who, at the same time, suffered from malarial cachexia, died with acute peritonitis. The necropsy revealed that it was due to rupture of an abscess of the liver into the peritoneal cavity and not to the dysentery. The results of this treatment are very rapid. Patients in a completely decrepid condition, with cool and clammy skin, small and rapid pulse, somnolent and apathic, when they entered the hospital with tenesmus, cramps in the calves of the legs and colicy pains as in cholera, were strikingly improved in four to five days. The torturous thirst and colicy pains with the sphincteric paralysis disappeared, the stools, which sometimes were as frequent as sixty in a day, bloody or sanguino-purulent and passed drop by drop, became feculent and soft. If the treatment were discontinued at this stage there would be quite certain to be a relapse, which would again yield to the remedy. It must be continued until the last traces of the disease have disappeared. If there be great tenesmus or excoriations, opium or cocaine in suppositories may be employed. If these fail then use disinfecting rectal injections. A fresh preparation of the drug is of great importance.

ACUTE BRONCHITIS.

In (*La Semaine Medicale* No. 64, 1893) the following is recommended in acute bronchitis :

℞ Salol .....
Terpene Hydrate, ana...25 cgms. (grs. iv)
Codene.....1 cgm. (1-5 gr.)

Sufficient for one powder. Make twelve such powders. One every two to four hours.

ACNE.

Professor Schwimmer (*La Semaine Medicale* No. 64, 1893), praises the following formula :

℞ Sublimed Sulpher.....
Starch, .....ana..... 5 gms. (ʒj ¼).
Black Soap..... 10 gms. (ʒijss).
Lard..... 30 gms. (ʒj).

Apply in a fine film, leave in place two hours. Then remove and wash the face in warm water and dust with rice or starch powder. After eight to fifteen days prescribe a simple ichthyol ointment.

# ABSTRACTS.

## LOSS OF HAIR.

Dr. G. T. Jackson, in writing on this subject, says that he has chosen the term "loss of hair," rather than baldness, because in my tables I have placed a number of cases in which absolute baldness was not present, but a general thinning of the hair, which, if not checked, would lead to baldness. Cases of defluvium capillorum coming on after acute illness are also included.

Of the 100 cases, 65 occurred in men, and 35 in women.

Of these, the nationality was: Canada, 1; Ireland, 1; Germany, 3; United States, 95.

Condition:

Married: 12 men; 16 women.
Single: 45 men; 16 women.
Widowed: 3 women.
Not recorded: 8.

Occupation;—of the men:

| | | | |
|---|---|---|---|
| Architect | 1 | Librarian | 1 |
| Bookbinder | 1 | Lithographer | 1 |
| Broker | 5 | Lawyer | 5 |
| Clergymen | 2 | Manufacturer | 2 |
| Clerk | 8 | Mechanic | 2 |
| Dentist | 1 | Merchant | 2 |
| Electrician | 1 | Physician | 15 |
| Farmer | 2 | Presser | 1 |
| Grocer | 1 | Waiter | 1 |
| Lecturer | 1 | None | 5 |

Of the women:

| | | | |
|---|---|---|---|
| Housewives | 16 | Glover | 1 |
| Singer | 1 | None | 16 |

Age at beginning:

From 10 to 20 years: 7 men and 7 women.
From 20 to 50 years: 44 men and 11 women.
From 30 to 40 years: 15 men and 11 women.
From 40 to 50 years: 1 man and 3 women.
Over 50 years: 2 women.

The greatest number of cases began in the 25th and 26th years, viz: 9 in each year. The next most frequent age was 22, with 8.

The baldness, or loss of hair, took the form of a general thinning..... in 6 mem and 19 women.

| | | | | | | |
|---|---|---|---|---|---|---|
| It affected the crown and temples | " | 13 | " | | | |
| It affected the crown alone | " | 32 | " | " | 10 | " |
| It affected the temples | " | 4 | " | " | 2 | " |
| It affected the temples and tonsure | " | 5 | " | " | 2 | " |
| It affected the tonsure | " | 4 | " | " | 2 | " |
| " " " occiput. | " | | | | 1 | " |
| " " " parietal region | " | 1 | " | " | 1 | " |

The following diseases were noted as complicating the loss of hair:

| | | | |
|---|---|---|---|
| Anæmia | 4 cases | Menopause | 1 cases |
| Chorea | 1 " | Metrorrhagia | 1 " |
| Constipation | 1 " | Over-training | 1 " |
| Dyspepsia | 11 " | Parturition | 3 " |
| Dyspepsia and Constipation | 5 " | Peritonitis | 1 " |
| Endometritis Chronica | 1 " | Pneumonia | 2 " |
| Gonorrhœa | 1 " | Spermatorrhœa | 1 " |
| Gout | 1 " | Sunstroke | 1 " |
| Headaches | 4 " | Urethritis Chronica | 1 " |
| Influenza | 1 " | Uterine fibroids | 1 " |
| Malaria | 7 " | Chancroid | 1 " |
| Measles | 1 " | | |

The cases of loss of hair following influenza, measles, parturition, pneumonia, peritonitis, and sunstroke were what are called defluvium capillorum, and came on from 1 to 5 months after convalescence.

The scalp and hair were found to be diseased in 88 per cent. of the cases as follows:

| | |
|---|---|
| Atrophied and bound down | 2 cases |
| Canities | 4 " |
| Eczema capitis 8 years before hair-fall | 1 " |
| Seborrhœa congestiva | 2 " |
| Sweating head | 5 " |
| Pityriasis | 10 " |
| Seborrhœa oleosa | 3 " |
| Seborrhœa sicca | 55 " |
| Fragilitas carinium | 3 " |

In 46 per cent. of the cases there was a history of baldness in the family, as follows:

| | MEN. | WOMEN. |
|---|---|---|
| Father only | 7 cases | |
| Father and paternal uncle | 2 " | |
| Father and paternal cousins | 1 " | |
| Father, paternal grandfather, and brothers | 1 " | |
| Father and brothers | 4 " | |
| Father, brother, and maternal aunt | | 1 case |
| Father and maternal uncles | | 1 " |
| Father, mother, and brother | 2 " | 3 " |
| Paternal uncle and brothers | 1 " | |
| Paternal uncle | 3 " | |
| Paternal uncle, maternal grandfather and uncles | 1 " | |
| Mother | 3 " | 2 " |
| Mother and maternal grandfather | 1 " | 1 " |
| Mother and sisters | | 1 " |
| Mother and brothers | | 1 " |
| Maternal grandfather | 1 " | |
| Maternal uncles | 1 " | |
| Maternal uncles and brother | 1 " | |
| Brothers | 2 " | |
| In family on both sides | 4 " | 1 " |

As possible contributory factors it was noted that:

1 patient constantly wore a close-fitting cap.
2 patients became worse after a short residence at the seashore.
2 patients smoked to excess.
21 patients soused their heads daily in cold water.

What deductions can we draw from the preceding figures?

1. As to the sex,—we find that 65 per cent. of the cases occurred in men. This is in accord with the well-known fact that men are more frequently bald than women. Therefore masculinity is a predisposing cause of loss of hair.

2. As to nationality,—no deduction can be drawn, as a preponderance of Americans was to be expected.

3. As to condition,—although we find 61 per cent. of the patients were unmarried, and but 28 per cent. were married, this does not allow us to draw any inference, because experience teaches that most men do not mind becoming bald half as much after they are married, as before they marry. Men tell me again and again, that they would not mind growing bald if they were married. It is a common experience that men are not so particular about their personal apperance after marriage as before, as they have other and more important things to think of. It is also to be observed that our tables show that the number of married and unmarried women is the same. With women the case is different from what it is in men, as the condition of the hair is for women a most important consideration from the standpoint of personal appearance, a fine head of hair being to them a matter of pride.

4. As to occupation,—here too, I should hesitate to draw an inference. If we took the figures alone, we would be compelled to think that doctors were especially liable to become bald. It is certainly suggestive that 26 per cent. of the cases occurred in professional men, this is in architects, clegymen, dentists, lecturers, librarians, lawyers, and physicians. If we add to these the 5 brokers, who certainly live under a constant nervous strain, we have 31 per cent. of the cases occurring in brain-workers. This is not intended to throw any slur upon the rest of the occupations mentioned in the tables. It, however, tends to suggest that active brain-work does predispose to loss of hair.

5. As to age,—it is evident from my tables that the majority of the cases of loss of hair begin before the thirtieth year of life, namely 69 per cent. We also see that in 67 per cent. of the men, and 31 per cent. of the women, loss of hair began between the 20th and 30th year. There is also a very marked difference between the sexes in the next decade; 18¾ per cent. in men, and 31 per cent in women. We also learn that the most critical years are from the 22nd to the 26th. Though the present paper is not intended to touch upon treatment, I would say that it is between the ages of 20 and 35 that we are most justified to expect good results from it.

6. As to the location of the loss of hair,—we find that 42 per cent. of the cases affected the crown alone, and 13 per cent. affected both the crown and temples. In 25 per cent. of the cases, there was a general thinning of the hair, and this was three times more frequent in women than in men. The tonsure alone was seen only 6 times, but it occurred with the receding temple 11 times. These figures bear out the well-observed fact that the top of the head is the location of baldness.

7. As to complicating diseases,—in only 52 per cent. of the cases did this factor enter into the field of our study. Of these anæmia, or diseases inducing anæmia, constituted nearly 79 per cent., namely: Anæmia, chorea, constipation, dyspepsia, endometritis, gout, headaches, malaria, metrorrhagia, over-training, spermatorrhœa, menopause, chronic urethritis and uterine fibroids. Acute and general constitutional diseases were met with in 9 per cent. of all the cases. Sexual disorders were met with only 4 times. A fair deduction from the figures is that anæmia is

a cause, or at least a predisposer, to loss of hair; and that the popular idea that loss of hair is due to sexual excesses is wrong.

8. As to diseases of the scalp and hair other than its fall. The scalp was diseased in 82 per cent. of the cases. Seborrhœa or pityriasis was present in 70 per cent. of the cases, and sweating or heat of the head was seen in 9 per cent. A history of an antecedent disease of the scalp was seen in but 1 case. From this the deductions are that seborrhœa is a most active cause of loss of hair that sweating of heat is a far more important symptom of danger to the hair than writers on baldness have commented on; and that an antecedent disease of the scalp other than seborrhœa is by no means so common as Pincus would have us believe.

9. As to heredity,—in 46 per cent. of the cases, there was a history of baldness in the family. It is certainly a most surprising fact, brought out by my tables, that in all the cases of loss of hair in women, there is a distinct history of the affection occurring on the maternal side; while in the 35 cases in which there is no history of maternal heredity, the men only are affected. It will be interesting to note, if further statistical studies show the same results. From the tables now presented, it is fair to deduce that loss of hair is markedly hereditary, and that it tends to descend in the same sex.

10. As to contributing factors,—in 21 per cent. of the cases, we find a history of daily sousing the head in water. This is by no means as great a percentage as is given by some other observers, but still great enough to suggest that the habit is detrimental to the hair. The other factors noted are so few as to be useless for deductions. They would tend to show, however, that the popular idea that wearing close-fitting headgear is a frequent cause of loss of hair is not true.

Summary: from the foregoing study of loss of hair, we can summarize as follows:

1. Men are far more prone to baldness than women, the proportion being as 65 to 35.

2. Neither the married nor the unmarried state exercise any influence in the production of baldness.

2. It is probable that active brain-work and nervous mental strain predispose to baldness.

4. The majority of cases of baldness occurring before middle life do so between the 20th and 30th year; and this is more marked in men than in women.

5. Anæmia, or disease that predispose thereto, are active causes of baldness.

6. Seborrhœa in all its forms is an active cause of baldness.

7. Sweating and heat of head may be regarded as danger signals,—foreshadowing loss of hair.

8. Heredity is a pronounced predisposing factor in baldness, and it shows a tendency to descend in the same sex.

9. The daily sousing of the head is pernicious to the preservation of the hair.

The study of ætiology is helpful chiefly as it teachers us how better to treat diseases. From the analysis of the causes of loss of hair, as here given, we may, I think, learn that it is essential for us to put our patients who are losing their hair, in the best possible physical condition; to cure, or at least alleviate, any disease of the scalp that may be present; and to forbid their sousing the head in water. —*Amer. Med. Surg. Bul.*

---

## INDICATIONS, TECHNIQUE AND RESULTS OF OPERATION ON THE APPENDAGES.

Schauta presented a paper on this subject before the German Gynecological Association at Breslau in May, 1893, of which the following is a synopsis:

1. The frequency of inflammatory diseases of the appendages is, according to Schauta's own material, 17.8 per cent.

2. A permanent return to normal conditions is not to be expected when the tube as a result of inflammatory changes has become as thick as a finger.

3. The diagnosis of the contents of the enlarged tubes (whether sterile, or containing gonococci, streptococci or

staphylococci) cannot be made with accuracy either from the history, the examination, or the course of the temperature.

4. Fever temperatures may be found before the operation, in cases of sterile contents, and completely normal temperatures where the tubes contain pus with streptococci or staphylococci.

5. The indications for operative treatment are present when the tube is the size of the finger and severe symptoms are present; in every case, however, where pus is present in the tube.

6. In case of pus during the operation, the immediate bacteriological examination of the pus is of great importance.

7. Where the tumors are of moderate size, and no pus is seen during the operation, it should be performed in the Trendelenburg position, and after complete separation of all the adhesions of the tubes with the surrounding parts, and thoroughly unfolding of the broad ligaments, continuous ligatures should be placed through the broad ligament and the isthmus of the tube, and then the tube should be cut away.

8. In the case of large tumors lying close to the abdominal wall the procedure is as follows: The peritoneum is opened, and if the opposite side is diseased to a less degree, the appendage of that side is removed; the large tumor is brought up against the abdominal opening and attached to the parietal peritoneum around a small circumference; the rest of the addominal wound is closed. Then the pus tube is punctured with a fine trocar, a portion of its contents aspirated, and immediately subjected to a bacteriological examination. If the pus proves to be sterile the sac is immediately opened to the extent of the exposed surface, washed out, the peritoneal sutures separated and the sac removed in the usual way. Should the pus prove to contain strepto- or staphylococci, the operation is temporarily suspended, and only after four or five days when the peritoneal cavity is completely shut off is the incision and drainage of the tube carried out.

9. In case of large pus sacs lying close to the vaginal vault, the opening from the vagina is indicated. Still in general the abdominal method is to be preferred since in the vaginal method one is denied the possibility of seeing the condition of the other side, or of operating on it, unless the method of total extirpation of the uterus according to Péan is followed.

10. In cases of medium sized tubes (size of an egg to that of an orange) laparotomy with careful avoidance of opening the sac is to be carried out. Should the sac burst, the pus should be immediately examined. If sterile, or containing gonococci the abdominal wound may be closed as usual; if containing strepto- or stapylococci Douglas's pouch which has been in contact with the pus should be drained after the method of Mikulicz.

11. The draining of Douglas's cul-de-sac is effectual first by drawing off the secretions, but principally by the speedy formation of adhesions which separate the part to be drained from the rest of the peritoneal cavity.

12. The mortality of Schauta's 216 cases from February, 1887, to April, 1893, was 13 or 6 per cent. Two of these, however, died of pneumonia.

13. The mortality of the cases of operations on the tubes where no pus or only sterile pus was found was 2.9 per cent. (four out of one hundred and forty-four); the mortality where gonococci were found in the pus was 9 per cent. (three out of thirty-three); the mortality where strepto- or staphylococci were found was 20 per cent. (three out of fifteen). Of the cases of the last category, with escape of pus, of six drained, one died, of five not drained, two died; of cases of laparotomy without escape of pus, and a second operation later, and of vaginal opening (four cases) none died.

14. For the estimation of the final results, Schauta has reports of 121 cases. One hundred were free from any disturbance, in 17 cases there was marked improvement, in four cases the old troubles persisted. The percentage of cures therefore was 82.6 per cent.—*Bost. Med. and Surg. Jour.*

---

Turpentine emulsions are used a great deal in typhoid and in low forms of fever with good results. But in some cases there is an idiosyncrasy to its use and stranguery of the kidneys may be brought on.

## OVER-CROWDED POPULATION AND THE PUBLIC HEALTH.

At a recent medical meeting some of our most distinguished physicians discussed the question of the dangers to the public health of New York from over-crowded population. The unanimous verdict reached was that over-crowding as it exists in our tenements is dangerous. This, to be sure, is something that almost every one had all along supposed to be self-evident; nevertheless, it is gratifying to have our axiomatic beliefs weighed and not found wanting. If no one debated except when some novel point was at issue, the silence would be most depressing. If the old idea appears in a new and moderately pleasing garb of words, we need ask nothing more—or will usually receive nothing more if we do ask it. In the present instance at least one of the speakers fulfilled this condition. He contrasted the death rate for a decade of the tenement-crowded metropolis with that of the neighboring city with its isolated dwellings. Considering chiefly such diseases as are directly contagious and those known to be markedly influenced by unhygienic surroundings, he found that in the case of scarlet fever, diphtheria, consumption, pneumonia, and intestinal disorders the death rate of New York relative to the population has been uniformly much higher than that of the other city, the difference in some cases being really startling. In case of only one disease—typhoid fever—has New York the advantage. This is explained by the fact that typhoid is a disease not directly transmissible from person to person, and one that never originates *de novo*, no matter how unhygienic the surroundings. Its germs must enter the body by way of the mouth, and the source of contagion is almost always the drinking water. New York, it would appear, has a better water supply than Philadelphia. Croton is not perfect, but it is better than Schuylkill.

Water aside, the doctors seemed agreed that we have not much in a hygienic way on which to plume ourselves; at least, not in our tenement districts. But then, as we have hinted, we knew or thought we knew all this before. The really significant question, and the one for whose answer we are anxiously waiting, is one made historic in quite another connection by a former owner of New York: What are you going to do about it? But at this inopportune moment came the silence. One physician did indeed hint that by the "refined methods of infanticide" in vogue—namely, the custom of leaving babies to the tender mercies of unsympathetic nurses, to be slowly poisoned with city milk, prepared foods, and other indigestibles—much was being done to reduce the rate of increase of our native population, and so indirectly the over-crowding. But he intimated that his Fifth Avenue patients were the ones most given to this practice, and spoke incidentally of families of fourteen or fifteen children in the tenements, from which one must infer that the reduction from this source is altogether out of focus, so to speak, and hence not to be depended upon.

Reference was made also to Mr. Greeley's well-worn advice to the young man. Considered merely as advice in the abstract, this is excellent. But in practice not only does the metropolitan-born young man decline to go West, but the young man whom nature, in anticipation of this advice, has caused to be born in the West, often fails to appreciate this prenatal kindness, and promptly annuls his advantage by migrating to New York, thus adding to the over-crowding.

Accepting the over-crowding as a fact to be reckoned with rather than overcome, another speaker hinted at building laws which should insure more air by allowing the construction of no tenement building more than two-thirds as wide as the building lot, after the Berlin method. But imagine a New York builder submitting to such a law as that! Before this worthy could be evolved to such a stage as that, our mechanical friends will have perfected their air-ships.

So after the discussion was over, here we were left in our crowded city, amidst dirt and carbon dioxide and micrococci and six-days-old milk, to struggle along as best we might, just as we had been doing all along, with little to console us except that relatively limpid Croton supply. However, even that is something to be thankful for, though it is to be feared that the tenement-dweller is too far removed from the prohibition atmosphere of Maine and Iowa and Kansas and too close to the corner saloon fully to appreciate blessings of this nature.—*Harper's Weekly.*

## OPERATIVE HERNIA AT THE FRENCH SURGICAL CONGRESS.

Except for a few contra-indications,—such as age, general condition, and volume of the hernial protrusion,—there is now almost no case where a cure may not be obtained by means of the operative methods. After hundreds of observations, it is pretty definitely settled that in most cases, at least, the surgical management of hernia results in a radical cure. Of course, however, there are instances of recurrence, particularly in two classes of cases,—those depending on the nature and variety of the hernia, and those depending upon the operator.

There are still some surgeons, anxious to extirpate the sac quickly, who spoil the operation by bungling methods. The superficial tissues are cut through quickly, the sac laid open in a hurry, dissected free and excised carelessly, and some sutures made rapidly. Such an operation cannot give desirable results.

Great care is necessary to dissect up the sac very high,—well into the abdominal cavity, and to reconstruct the canal and the columns of the rings.

This operation, to be successful, must be methodical, is always delicate, and often long, and not a single detail can be neglected. Some surgeons may have more recurrences than others. Some herniæ no matter how skilful the surgeon, particularly the very voluminous herniæ, passing through large rings, with lax and non-resisting muscular walls, are very apt to recur. These cases require the most particular attention from the surgeon.

Zaucarol (Alexandria) considers that the danger of a radical cure is much less than when the hernia is not subjected to operative methods. In 30 cases he has only one slight recurrence. His first operation was performed seven years ago, and the last four months ago. Ten of his cases were operated upon according to Lucas Championierre's method, and the one recurrence was among these cases. Eight were treated by an English modification of this method, which consists, after opening the sac, in detaching the neck as high up as possible, and suturing and replacing it in the cavity. Two thick silk threads, in the shape of an X, are passed through the inguinal canal. Three or four deep threads are then applied perpendicularly to the incision. These are tied, the skin is then sutured and the two deep-crossed threads are tied.

Thiriar (Brussels) described a new method in which the sac having been resected and the stump returned to the belly, he employed a plate of decalcified bone between the stump and the abdominal wall. The size of this plate varies according to the size of the opening. It is fixed in position by catgut sutures.

In 20 patients with voluminous herniæ, Thiriar ascertained that this bony plate was absorbed and replaced by hard and resistent scar-tissue, which has never yielded, so that not one recurrence has taken place.

Schwartz did not resort to bone-transplantation, but to a kind of myoplastic operation. This consisted in the following:

In cases of large openings and very thick hernias, it is absolutely necessary to consolidate the hernial region. Skin, tampons, catgut, calcined and decalcined bones, etc., have been employed for this purpose.

He had, some time ago, to operate for an enormous femoral hernia, the most voluminous he had ever seen. It occupied the entire half of the thigh and issued through a ring which permitted the easy passage of two fingers.

To close this large opening he dissected a flap from the long adductor of the thigh, turned it down over the open ring, and sutured its entire circumference with silk.

The empty cavity was covered, as much as possible, with cellular, fatty, and fibrous tissue. The operation was performed four months ago, and the patient, though not having worn the truss which had been prescribed, had, at the level of the ring, a supple and resisting wall.

In inguinal hernia, having split the canal or ring, the sheath of the great tight rectus muscle is opened along its external margin and a large flap, with a long pedicle, is detached from it and pushed outside so that it passes behind the interior column of the ring. It is sutured to the canal and orifice, the cord being passed below its inferior border; the columns are reunited with silk and the muscle inserted beneath. The sheath of the rectus is closed again, the operation being completed in the usual way.—*Gaz. des. Hopitaux.*

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

THE ANNALS OF GYNECOLOGY AND PÆDIATRY

for November. Dr. M. S. Marcy contributes an excellent paper on

**Abortion,**

considering only the criminal and artificial sides of the subject. He condemns in unmeasured terms the production of abortion for any other reason than the saving of the life of the mother. No matter what the station in life of the unfortunate woman, the author believes that it is the duty of the physician, when he has the proof against the abortionist, to report such cases to the legal authorities.

In regard to artificial or necessary abortion, the cause which most often forces the physician to the operation is the pernicious vomiting of pregnancy. The author asserts that the diagnosis is not so simple as at first seems apparent. Gastric ulcer, chronic gastritis, cancer of the stomach or liver should be carefully eliminated. The hygienic part of the treatment is very important in the milder cases and is not to be overlooked in the graver ones. The author advises that the patient take a light meal of any food that can be retained, an hour or two before arising from bed. The caprices and fancies of the patient should be respected. When all food taken into the stomach is rejected, nutrient enema must be tried. Early attention should be given to the gynecological treatment of the case. If uterine displacement exists, gentle efforts should be made to reduce the organ to its natural position, not forgetting however that the normal position of the pregnant uterus is one of anteversion or even mobile anteflexion. By far the most efficient procedure, the author believes, is the treatment of the vaginal portion by means of the application of a 10 per cent. solution of nitrate of silver through a cylindrical speculum. After exhausting the hygienic, medical and gynecological treatment the attendant should terminate the pregnancy by artificial means. The author takes the position that it is not only the physician's duty, but that he is criminally negligent if he allows his patient to die from pernicious vomiting of pregnancy without evacuating the uterine contents. The operation to be successful, should be performed early without waiting for the patient to become exhausted.

Dr. William H. Humiston contributes a paper on

**Treatment of Diseases of the Uterine Appendages.**

For the vaginitis, active endometritis and tender appendages the result of gonorrhœal infection, and which would develope into pyosalpinx, the author advocates the following treatment: "The patient should be put be to bed and made to stay there. A one to three thousand bichloride douche following the hot-water douche, of half an hour's duration, twice a day, after which the vagina is well dried, and thoroughly dusted with powdered boracic acid and aristol, equal parts, and the vaginal walls kept apart by antiseptic non-absorbent tampons. This treatment faithfully observed for one week will so remove the more acute symptoms that curettement can be made." After curetting thoroughly, the author applies the compound tincture of iodine freely to the uterine cavity. The patient should remain in bed for ten days after the curetting; she should be treated locally until every trace of the disease has been removed. When the case has advanced to the formation of pus, laparotomy and the removal of the pus collection is the only rational treatment.

In regard to the use of electricity, the author states thae he values it highly, and in the catarrhal forms of endometritis in young girls and primiparæ a cure can be obtained if sufficent time be given. The author also regards electricity as a valuable aid in the diagnosis of doubtful suppuration. The positive intra-uterine electrode is introduced to the depth of one inch in the uterine cavity and a current of forty to fifty milliamperes gradually applied. If the patient is oversensitive to the current, and complains of great pain, which persists for several hours after its application, you have a case of suppuration. If inflammation or congestion is present there will be a sense of relief, which will continue for a day or two after the application.

**The Results of Vaginal Hysterectomy**

is the title of a paper contributed by Dr. Andrew J. McCosh. The author considers the results of his own operations for cancer and for prolapse. He has performed the operation for cancer sixteen times with no deaths. In regard to the technique of the operation, he prefers the use of silk ligatures to the clamps for securing the broad ligaments, and he states that he has seen no great disadvantage from the use of the ligatures. The technique of the operation is thoroughly discussed in the paper and the subsequent histories of the sixteen cases operated on reported. The author states that while there are a certain number of these cases suitable for abdominal hysterectomy, he has never seen one which, in his opinion, was suitable for sacral hysterectomy and he is of the opinion that when a uterus cannot be removed by the vagina or abdomen it is better to refrain from any radical operation.

In regard to vaginal hysterectomy for prolapse, the author reports six operations with but one success. It is his judgment, therefore, that vaginal hysterectomy for the cure of aggravated prolapse is an unsatisfactory procedure, and that, as a rule in such cases, abdominal hysterorrhaphy is the preferable operation.

Dr. X. O. Werder discusses the

**The Present Status of the Treatment of Uterine Fibroids.**

Electricity he regards as having failed to accomplish the good results claimed for it. It is useful mainly for the relief of symptoms in carefully selected cases and can in no sense be regarded as curative. Galvanic puncture he regards as fully as dangerous as hysterectomy in skilled hands and not to be compared in its results to operative measures. The author discusses the relative merits of vaginal enucleation, enucleation of the tumor by laparotomy, and suprapubic hysterectomy. The abdominal and extra-peritoneal methods of performing hysterectomy are also considered and the author decides that while his preference in good, vigorous subjects would be total abdominal hysterectomy, he would feel that the weak reduced patient had a better chance for life with extra-peritoneal treatment of the stump.

Dr. Andrew F. Currier contributes a short paper on

**Myoma Uteri and its Treatment.**
